FEDERAL ENERGY REGULATORY COMMISSION

- - - - -x
IN THE MATTER OF: :
PJM INTERCONNECTION, LLC : Docket Numbers
TECHNICAL CONFERENCE - COMPENSATION FOR : PL04-2-000
GENERATING UNITS SUBJECT TO LOCAL MARKET :
POWER MITIGATION IN BID-BASED MARKETS :
- - - - -x

Hearing Room 2C
Federal Energy Regulatory Commission
888 First Street, NE
Washington, D.C.
Wednesday, February 4, 2004

The above-entitled matter came on for technical
conference, pursuant to notice, at 9:10 a.m.

BEFORE:

MICHAEL COLEMAN, presiding

OMTR

1 APPEARANCES:
2 FRANK NAPOLITANO, Lehman Brothers Inc.
3 JONATHAN BALIFF, Credit Suisse First Boston Corporation
4 MICHAEL THOMAS, Calpine Corporation
5 WILLIAM HOGAN, Harvard University
6 MICHAEL SCHNITZER, The NorthBridge Group, representing
7 Exelon Corp.
8 ROY SHANKER, Consultant to generators & Financial market
9 participants
10 DAVID PATTON, Potomac Economics, MISO Market Monitor
11 JOE BOWRING, PJM Market Monitor
12 ROY THILLY, Wisconsin Public Power Inc.
13 ABRAM KLEIN, Edison Mission Marketing & Trading
14 JOHN ANDERSON, John Hancock Financial Services
15 JONATHAN BALIFF, Credit Suisse First Boston Corporation
16 MARK REEDER, New York Public Service Commission
17 STEVE CORNELI, NOG Power Marketing Inc
18 BOB ETHIER, ISO-NE Market Monitor
19 GUNNAR JORGENSEN, Northeast Utilities/Select Energy
20 HOWARD NEWMAN, Warburg Pincus
21 DANIELLE JASSAUD, Public Utility Commission of Texas
22 JOHN MEYER, Reliant Resources, Inc.

P R O C E E D I N G S

(9:10 a.m.)

MR. COLEMAN: Good morning. Welcome to the Technical Conference in Docket PO04-2, Compensation for Generating Units Subject to Local Market Power Mitigation bid-based markets. I'm Michael Coleman of FERC Staff. I'm the moderator for today's conference.

The purpose of today's technical conference is to engage industry experts and market participants in a meaningful dialogue on the issue of appropriate compensation for generation subject to local market power mitigation.

The issue was formally teed up in a PJM docket last year. The concern, however, is not limited to PJM. All regions of the country have local transmission-constrained areas where generation owners can exercise local market power due to concentration of ownership and generating units in that area where the uniqueness of a specific generating unit can solve a local reliability problem.

We will hear today about how these situations arise, what steps have been taken to date to mitigate prices paid to such generators, what further needs to be done to resolve RMR problems, who should be responsible for implementing solutions, and who pays.

There are many different solutions that are

1 appropriate for different regions or different fact
2 patterns. There may be options for the same area. The
3 solutions may vary from improving the market design and
4 pricing, to incentives to attract and retain infrastructure
5 solutions to auctions to identify the most effective and
6 efficient infrastructure and response.

7 That's a lot of ground to cover, so let me lay
8 out a few logistics: Conferences are being held today and
9 tomorrow. Today will be a broad overview of principles, the
10 pricing arm of units across the country.

11 Tomorrow will be a more granular discussion of
12 the proposals in the PJM EL03-236 docket. We have a full
13 house and a packed agenda today, with an oversubscription of
14 speakers.

15 This basically reflects the interest in and the
16 importance of the RMR issue. To accommodate those who were
17 unable to present today, we are allowing parties to file
18 comments in the PL04-2 docket. We ask that those comments
19 be filed by February 27th. We'll probably issue a notice
20 sometime later on this week. That will formally indicate a
21 February 27th comment date.

22 The technical conference is being transcribed,
23 and we will let you know when the transcript is available.

24 Today's agenda and format: This morning we have
25 an opening presentation on capital formation for power

1 infrastructure. Many of the long-term solutions for RMR
2 issues we're likely to hear about today involved
3 infrastructure additions, and the ability to attract
4 investment in such infrastructure will be key to those
5 solutions.

6 After a couple of speaker comments to supplement
7 the presentations and perhaps a question or two, we will
8 immediately move to our second panel for opening remarks.
9 To allow sufficient time for an interactive discussion,
10 we've asked speakers to limit their remarks to five to seven
11 minutes.

12 A clock is provided to assist you and me in time
13 management. Please help me out on this one. We'll take a
14 15-minute phone and restroom break at about 10:30. After
15 that break, we'll convene with Q&A until the lunch break,
16 which is scheduled from 12:15 to 1:30. The afternoon
17 session will follow the same format as the morning. The
18 first afternoon session will begin at 1:30 and will focus
19 more on Northeast market experiences with local market power
20 mitigation.

21 We'll take a 15-minute phone and restroom break
22 at the conclusion of the first panel in the afternoon, and
23 start up again at 3:30 for the second panel, which will
24 address RMR issues and experiences in other parts of the
25 country, including Texas, California, and the Midwest ISO

1 region.

2 With that, I'd like to turn the floor over to
3 Frank Napolitano of Lehman Brothers, for an opening
4 presentation. Frank is manager and co-head of Lehman Global
5 Power Group, and has graciously accepted our invitation to
6 provide us with a short introductory presentation. Frank,
7 welcome.

8 MR. NAPOLITANO: Thank you, and good morning. I
9 have a slide presentation here of four or five pages. The
10 intent is to provide a framework for a discussion, and it
11 will be a bit of a review of the past, and it will bring out
12 some observations that we at Lehman Brothers are seeing in
13 the markets today, particularly around financing
14 infrastructure.

15 It will probably not delve as deep into the load-
16 pocket issue as many of the other, more technical speakers
17 will go into, but we will be happy to field some Q&A on
18 those.

19 (Slide.)

20 MR. NAPOLITANO: Starting on page 1, you see four
21 stacked bar charts that describe four regimes I'd like to
22 lay out here as the framework for the discussion. Regime A,
23 all the way on the left, is meant to demonstrate the
24 composition of a traditional utility, cost of service
25 capital structure.

1 These numbers can be debated, plus or minus, but,
2 in general, roughly 50 percent of the capital structure
3 would be represented as debt. That debt would be considered
4 recourse and corporate in nature.

5 Around five percent of the capital structure,
6 plus or minus, is generally preferred, and around 45 percent
7 of the capital structure is common equity. This is viewed
8 by investors -- the perceived degree of relative risk of
9 this regime versus the rest on the page, this is kind of
10 viewed as the lowest-risk regime, and that capital structure
11 demonstrates that risk.

12 The next regime that I demonstrate here is what
13 is called the contracted regime. I call it the PURPA
14 Contracted Power Project Regime.

15 MR. PERLMAN: Frank, your slides are not showing
16 up. Maybe you can describe very briefly, what you're
17 talking about, as well as describe it. They're not showing
18 up on the screen for the audience.

19 MR. NAPOLITANO: We have handouts as well. In
20 Regime B, this shows what the strength of a contract, a
21 rateable contract that is viewed by the markets as a
22 creditworthy instrument, what this does to the capital
23 structure, as you look at relative risk, and as you can see
24 from this stack bar chart, roughly 80 to 90 percent of the
25 capital structure of a project financed off the basis of a

1 revenue contract that I just described, could be debt.

2 That debt in this case is non-recourse and
3 project finance. This is different from recourse and
4 corporate debt. This is highly specific debt, where the
5 payback on that debt, the return on and of the capital of
6 debt is wholly dependent upon the operations of the project
7 and the revenue that the contract generates.

8 The remainder of the capital structure in these
9 circumstances was typically equity. As folks remember,
10 these PURPA contracts are kind of old and cold at this
11 point, but the long-term nature of those contracts still
12 survives. Many of those contracts are still operative in
13 nature, and many of the projects that were financed using
14 these contracts, have seen a fair amount of appetite in the
15 M&A market over the past two years as financially distressed
16 parties look to raise capital in the most efficient way
17 within their means.

18 What they found was that the value of these
19 assets backed up by these contracts, in some cases were more
20 valuable to them in a sale context than selling their own
21 corporate securities, either debt or equity, to the extent
22 they had liquidity in the markets to sell those corporate
23 securities.

24 The next regime that I describe here on this
25 chart, I call Regime C. This is kind of the highest regime

1 risk on the page.

2 This is really meant to illustrate the EWG
3 Merchant Power Projects, largely gas-fired generators,
4 green-field, and construction in nature, that were financed
5 during the boom times of the power market, leading up to the
6 energy crisis.

7 Typically, these projects did not involve long-
8 term contracts; they involved merchant revenue streams that
9 the market, both debt and equity, need to become comfortable
10 on with respect to what the composition of those streams
11 would be.

12 A fair amount of expertise was brought to bear in
13 the financing of these projects through the use of
14 consulting reports and other types of measures to educate
15 the investor base as to what a reasonable view of revenue
16 could and should be.

17 However, the key point was that there were no
18 underlying contracts to provide a floor to those
19 estimations, so this was real risk. As you can see from the
20 capital structure of these projects, ironically, a fair
21 amount of non-recourse and project debt was available in the
22 market at that time to finance projects of this nature, and
23 the remainder of the capital structure is equity. We kind
24 of list 60 to 80 percent debt against merchant power plants
25 during those time periods.

1 This showed that the market at that point in
2 time, the financing markets, were willing to buy into market
3 development through the merchant stratification of the
4 markets, opening of markets, many, many concepts that were
5 seeking to be employed from a policy perspective.

6 The financing markets showed they were willing to
7 sort of buy into that structure, however, the crisis
8 involved a turn, and folks learned what the nature of
9 merchant versus contract really meant. The folks who
10 learned the most in that story were the debt providers.
11 We'll talk about that more in a moment.

12 Largely, my remarks, as you will see, are from
13 the debt perspective. Equity, in my view, is a derivative
14 of the risk debt is going to take. This leads us to Regime
15 D.

16 Here we are in a post-energy crisis environment.
17 This conferences is about new infrastructure investment in
18 selected cases. Where will the capital markets draw the
19 line with respect to a capital structure and/or any capital
20 flowing into these circumstances?

21 I will refer to these various regimes on the
22 following pages. I'm now turning to page 2.d

23 This slide is entitled Assorted Financing:
24 Lessons Learned. During Regime C, the risky part of the
25 market, this risk can be very long; it can be very pointed.

1 We tried to capture some of the larger items here.

2 As I mentioned, this concept of buying into,
3 there were several assumptions and parameters that were
4 assumed to be balanced, but were tested under duress and
5 found to be flawed.

6 In general, some of the categories are as
7 follows: Disclosure. This is a very broad word. What can
8 it mean to something in particular, like merchant power
9 financing?

10 Well, it really relates to the second item, which
11 are in our consulting reports on commodity price dynamics.
12 If you were an investor and looked at the scope of some of
13 these reports, you may have believed that that scope
14 encompassed every risk that you should be knowledgeable
15 about and possibly provided mitigants and understandings of
16 those risks.

17 That, in all cases, wasn't necessarily the case,
18 so you could argue that the universe of investors did not
19 have a full and transparent view of the risks that they
20 faced as to market development risk and the onset of many of
21 these financings.

22 Many of the various markets, both regionally and
23 nationally, were at their incipient stages. They had not
24 been tested under duress. There had not been a long track
25 record of workability under those markets. And as we have

1 learned in California and other places, market development
2 risk was a real investment risk that many may not have
3 thought was a real risk at the time of those investments.

4 When you look at the composition of the capital
5 structure for a typical merchant power plant under Regime C
6 and you saw all of that non-recourse project financed debt,
7 and then we've learned now, post-crisis, what risk that debt
8 really took, you could assume that that debt assumed an
9 equity level of business risk within the capital structure.
10 I think that's a valuable lesson learned. That will
11 certainly be on the minds of debt investors as they go
12 forward and think about new investments.

13 There was a concept, however, in the industry,
14 both the market participants, i.e., folks building
15 infrastructure, and those financing it, that there would be
16 some nature of self-regulatory aspects to capital flowing
17 into infrastructure investments.

18 I had heard from folks that the capital markets
19 will never let a bubble be built. Clearly, that was not the
20 case. So, depending upon that self-regulatory nature of
21 capital, was not a very good assumption.

22 There was a further assumption that bankruptcy in
23 the utility sector was a far-off concept, one that could not
24 actually be realized. We have learned that in not just
25 utilities, broadly, but power, more broadly, bankruptcy is a

1 real phenomenon; it can really happen; it really has, and it
2 could again.

3 And so there is no big brother that would step
4 into something like a public policy infrastructure situation
5 to sort of call a time-out and stop some circumstances from
6 happening. Those circumstances happen. Debt investors now
7 know that, as do equity investors, and folks are aware of
8 that situation.

9 The concept of non-recourse debt versus recourse
10 -- non-recourse, again, very specific to the infrastructure
11 being invested in. What folks have learned, post-crisis, is
12 that non-recourse really means that debt owners can now be
13 equity owners upon a bankruptcy type situation.

14 Under these circumstances, debt investors who
15 invested non-recourse and possibly thought there might be
16 some future infusions of capital, although none were
17 required or mandated, but they thought that might be the
18 case, now know that folks are going to act in their economic
19 best interests when tested under duress.

20 Under these circumstances, these debt investors
21 are now, in the case of merchant power plants, in
22 particular, asset owners. That's a new transition within
23 the sector.

24 There's a new owner base within the power sector.
25 Clearly, those investors are not meant to be long-term

1 owners of infrastructure capital, at least not in that
2 method.

3 Lastly, really, this is a financial mechanism,
4 but liquidity facilities -- I mentioned before about
5 liquidity that might flow voluntarily into a non-recourse
6 situation. In many cases, had some of the owners of those
7 plants, the equity holders, wanted to do that, they found
8 out that they didn't have the money themselves; they weren't
9 getting it from free cashflow from operations, and they
10 couldn't get it from additional lending facilities, from
11 institutions. So they had no choice in some cases but to
12 walk away from their equity.

13 One of the lessons learned, again, is that there
14 is really no good substitute for traditional liquidity
15 facilities in the event that additional cash is required to
16 be injected into systems.

17 Page 3, Implications for Future Infrastructure
18 Investment: Really, Bar D, where will the market draw the
19 line with respect to new capital flowing into these
20 situations? There are some real-world things we have deal
21 with.

22 The pain amongst many of these financing players
23 is still fresh. It's not old. We may argue that the
24 markets may have stabilized for the time being, both from a
25 financial and a fundamental standpoint, but the pain is

1 still fresh and the historical, institutional investors --
2 which are the bank markets and the long-term fixed income
3 markets -- they have long memories. They sort of remember
4 what's happened here, and they remember privatizations in
5 foreign countries where they experienced very similar
6 characteristics with respect to their investments so close
7 to the onset of a new market and folks are wary.

8 There are new players and some non-traditional
9 players. This is smart or hot money, as it may be called on
10 the street. These are private equity players, hedge funds
11 and other forms of private capital.

12 These are folks who are opportunistic. They
13 have liquidity; they have a desire to play where there's an
14 opportunity with respect to a need for something as
15 fundamental as infrastructure, and a lack of possible
16 willing capital or capital that is priced for the large-risk
17 premium to flow into those circumstances.

18

1 What these folks have, to their advantage, is the
2 hindsight for those things that have recently gone wrong,
3 and it's clear that they are going to be cognizant of those
4 as they think about making their next investments. The
5 market, in general, is probing for workable models of the
6 past.

7 You hear "back to basics" in so many different
8 ways. You hear it in the investment paradigm of capital
9 flowing into infrastructure. You hear it from the
10 management of companies that reside in the sector and are
11 players, the owners of the assets in the sector.

12 And you really hear it from a market standpoint
13 as to I want to understand how this market works. Is it
14 transparent enough that I can observe this market working in
15 the way you're saying that it's working, so that I can
16 monitor the performance of my investment, either a physical
17 investment or a financial investment?

18 And, lastly, there is money available to the
19 sector. You may hear that from other speakers throughout
20 the course. That money, as we talked about, has the
21 advantage of an educated past, a recently-educated past, and
22 it's able to evaluate risk and return right now.

23 Where does it feel most comfortable, and where
24 will its costs be released with respect to financing?
25 Clearly, where things are most certain: There are many,

1 many thoughts in the sector about what do we do now with
2 respect to disparate markets and jurisdictional imbalances?

3 The left side of the spectrum is to bring it all
4 back to where it was; the right side of the spectrum is,
5 force it into all open and capital can be priced accordingly
6 within that spectrum.

7 The clear question, though, is time. The more
8 certain things are made, sooner, the more quickly capital
9 will flow in a rateable fashion, and the sooner, possibly,
10 some of these fundamental technical issues, these asset
11 issues, can be resolved.

12 To the extent that the markets, as they are
13 designed, will continue to have an implied level of risk and
14 possibly not clear and transparent risk, capital will
15 eventually flow, but it may cost more than it should for a
16 certainty that may be eventually be reached at some future
17 point in time.

18 I talk about optionality here, and this may be
19 too technical for this broad of an audience, but I'll give a
20 go at it. Capital feels comfortable with the prospects of
21 investing in an asset which displays characteristics of a
22 deep-in-the-money intrinsic option.

23 Optionality has two characteristics to it:
24 Extrinsic, which is volatile, and, some could say,
25 veritable; and, market-based and intrinsic, which is

1 certainty. The most certain form of a revenue stream, as I
2 mentioned before, is that which can raise the most debt,
3 which is very cheap cost of capital in today's market,
4 that's a contract.

5 Some assets resemble contracts in nature,
6 fundamentally something like a low-cost coal plant in a gas
7 marginal region. That can look like a contract. It's going
8 to be evaluated; it's not as good as a contract, but it can
9 look like one, something like a cost-of-service rate base
10 that might have some performance-based up sides. That looks
11 like Regime A, something like a contract.

12 Lastly, jurisdictionally undisputed, bilateral
13 contracts where there is no argument to the validity of the
14 contract. Well, that's a contract and that's certain. What
15 we are saying is that the near-term balance will favor the
16 flow of capital against where there is transparency and
17 certainty.

18 Slide 4, I guess, is a layman's way of trying to
19 talk about the complexity of what an investor may see in
20 something like a load pocket, especially a wholesale load
21 pocket. There's a wide degree of generation participants in
22 that market, both the fuel type and the nature of their
23 assets and how it meets load-serving needs

24 There are also things that pop into the mix like
25 peaking generation, whether it's market-based or just built

1 by an incumbent, and that incumbent might have the advantage
2 of tax-exempt debt. There are things like distributed
3 generation, combined heat and power renewables, which are
4 somewhat social programs, but valid, and in the market, that
5 needs to be understood.

6 On the transmission side, there's intragrid
7 situations and intergrid, meaning the connection of grids to
8 make regionality greater, the concept of super regions, and
9 all of these assets right now, from a financing market
10 standpoint, are kind of in play.

11 Whether there are existing assets suitable for
12 the M&A market, which would involve somebody needing to
13 finance that M&A transaction, or whether they are new -
14 build, requiring new construction within the pocket, or
15 whether they are going to be contributed possibly, the in
16 the case of transmission, to some greater whole, all of
17 those have financial implications to the current asset
18 owners, to the new asset owners, and to how the capital
19 structure of the various participants in that pool are
20 constructed and how the capital will then behave.

21 So, it's fairly complex. You have parties who
22 are clear entrepreneurs and profit-incented, and you have
23 parties who are not necessarily profit-incented, but
24 reliability-incented and subsidized with cheaper capital.

25 All of that sort of stirred around in one soup

1 where the question is then put before the house, to the
2 entrepreneurs or the companies which are entrepreneurs by
3 nature: How do you then come and participate in the next
4 asset-based solution? That is just quite difficult to
5 navigate.

6 The last page really goes back to Regime B, which
7 we consider to be the time-proven financing method for these
8 types of initiatives. If you look at bilateral PURPA
9 contracts, the way they were constructed, they generally
10 separated fixed and variable components, not unlike gas
11 pipelines.

12 And the fixed component was meant to cover
13 certain items, and the variable component was meant to cover
14 off certain items. The financing markets generally viewed
15 that as a rate base and financed it as such, but it favored
16 an arbitrage of debt over equity.

17 When you looked at the total composition of debt
18 in the capital structure, you saw numbers that were higher
19 than the utilities who were the obligors on the power
20 purchase agreements.

21 That worked; it still works; those contracts are
22 still valid; folks are buying assets to get to those
23 contracts and leveraging it again. The employment of a
24 similar financing mechanism at this sensitive point in time
25 with respect to the infrastructure on power via grids or

1 generation, we believe, would be extremely well received by
2 infrastructure investors.

3 The contract would mitigate risks that are the
4 unknowns, therefore, the equity capital that will flow
5 against a debt to round out the capital structure will
6 inherently have less risk, and, therefore, should
7 theoretically charge less of a return. That's a way of
8 bringing low-cost resources. Maybe it's not the preferred
9 way, but it certainly is a way of bringing low-cost
10 resources and assets into the marketplace.

11 So, who might be the determinant of what is
12 needed and how it gets priced? I guess that's the subject
13 of the debate.

14 We see one alternative as being some objective
15 clearing originator, not necessarily the load-serving
16 entities. It could be whoever is in charge of the
17 reliability of that market. It kind of sits in some taller
18 seat to what we all think exists, and they can see how all
19 these assets are flowing together and the needs of end-use
20 customers are flowing together. And that entity that may be
21 responsible for that reliability could possibly be in charge
22 of gestating the next assets, whether they be transmission
23 or generation, and how that asset should be priced.

24 That's the conclusion of my prepared remarks.

25 MR. COLEMAN: Thanks, Frank. We're going to move

1 to some additional comment from Jonathan Baliff of CSFB.
2 Jonathan, welcome.

3 MR. BALIFF: Thank you very much. I'm Jonathan
4 Baliff, Director of the Global Energy Group at Credit
5 Suisse-First Boston. I'm going to further some of Frank's
6 comments concerning really what I consider the fundamental
7 transformation and change of the bank market in financing
8 generation assets and the overall energy sector and utility
9 sector going forward for the next, I'd say, at least five to
10 ten years.

11 Over the last three years, there has been a huge
12 upheaval in the bank markets. And when I'm talking about
13 bank markets, I'm talking about the loan market, not
14 investment banks, not the traditional way that corporates
15 and project finance vehicles or generation assets were
16 financed, which was primarily with floating-rate, short,
17 what I would consider three-year term loans to make these
18 plants happen, whether they were in a load pocket or not.

19 This was the way most of the issuers financed
20 their projects, whether it be the unregulated Calpine,
21 Dynegy, et cetera, or if it was the regulated. They used
22 bank loans.

23 This has fundamentally changed since the
24 bankruptcy of Enron. Over the last three years, we have
25 seen a shrinking of a bank market which is normally a \$900

1 billion market, to a \$600 billion market.

2 We've seen an increase of a new participant, a
3 new loan provider called the institutional loan market. We
4 also call it the B-Loan market. That has grown from
5 approximately \$250 billion to over \$400 billion.

6 There is a fundamental reason this is happening.
7 I want to use an example of the housing market.

8 Really, when you went to go get a loan for your
9 house, 10 to 15 years ago you went to a bank and they
10 provided you a loan, and they held that loan. But then
11 there came a new market called the collateralized loan
12 market or CDOs, CMOs.

13 This was able to take the risk inherent in a lot
14 of different loans, pull them together, and allow investors
15 to really just diffuse the risks of these loans. On the
16 equity side of the housing market, what we saw was the
17 RIETs. The RIETs are equity-transformed pools of money that
18 go in and buy either commercial or residential real estate.

19 This provides, again, a diffused market for
20 equity, so the equity providers, which normally are the
21 developers of housing markets, were able to diffuse their
22 risk. This is why I think you saw that Wall Street Journal
23 article about two weeks ago about why in this economy, even
24 though we have a booming housing market, we have a reduction
25 in economic growth, that many of these developers in housing

1 didn't go bankrupt. Why? They diffused their risk. CSFB's
2 premise is that that's exactly what is happening in the
3 overall bank market.

4 What we have happening is that the institutional
5 loan market are pools of investors, primarily hedge funds
6 but also insurance companies, providing bonds to many of the
7 same issuers that used to get bank loans. Because the bank
8 market has pulled back, primarily because CSFB, Lehman, and
9 a bunch of us are owning assets right now, which I can tell
10 you is something that we do not want to do -- because of
11 this, we have been able to find pools of investors who will
12 go out and make floating-rate loans on much better terms
13 sometimes than what was available in the project finance
14 market and even in the corporate market for some of our
15 issuers.

16 Why does an investor want to go to a hedge fund?
17 Again, these are unregulated pools of capital. They
18 normally require much higher return rates than a normal
19 bank.

20 Why are we seeing these guys entering, and why
21 are issuers accepting this money? Primarily because it is
22 very difficult right now to get a bank loan. They are over
23 360 more days in duration. Why? Because of the risk
24 capital that is imputed by the regulators on banks is
25 excessive; it's significant, okay?

1 It makes it very costly and the only way that we
2 can actually make those loans is if we get subsidized with
3 investment banking business or trust business or other
4 ancillary fee-based businesses. That's one way that we'll
5 do it, but other than that, really it comes down to the
6 institutional loan market, which can provide five- to nine-
7 year, floating-rate capital.

8 This is extremely long capital, and it's
9 provided. It's one of the reasons why you see many of the
10 companies that are in severe distress, such as Reliant, et
11 cetera, get a second lease on life, literally because of
12 these longer-term floating-rate loans that are provided by
13 these institutions.

14 The other reason that they like to take them or
15 that the issuers like to use this money is that there is
16 less care and feeding. If you're a banker and you make a
17 loan to an institution, you have a yearly bank meeting, you
18 get a steak dinner, you get golf at a nice place.

19 Guess what? These institutions, they don't care
20 about that. And this is the fundamental transformation the
21 bank wanted. Why don't they care about that? Because they
22 can trade out of their paper. There is liquidity in this
23 marketplace.

24 A bank that used to make a loan was the lender of
25 last resort. That bank, whether it be Credit Suisse-First

1 Boston or Citigroup, could not trade that loan. We held it
2 in our own bank as an asset. We had to mark it down if it
3 wasn't performing.

4 Right now, we have seen an explosion since Enron,
5 of what we call the credit default swap market. This is a
6 market in which I can or CSFB can trade out of their
7 position in companies to manage our risk portfolio.

8 Just to give you an example, three years ago,
9 before Enron, we had roughly 12 trading parties that Credit
10 Suisse-First Boston would trade with in its credit default
11 swaps, 12 very large parties. There are over 150
12 counterparties that we have now in trading. It is an
13 extremely liquid market.

14 So that is one of the other reasons issuers like
15 to go to the institutional markets. They know they don't
16 have to do a lot of care and feeding of these institutions.

17 Then, finally, when it comes to actually the RMR
18 or financing the RMR market or assets in the load pockets,
19 this is a market that is going to tap the B-loan market
20 significantly. Why? One, longer-term financing, and it can
21 also be cheaper financing than project markets.

22 Second, if you can mitigate the significant risk
23 associated with RMR -- and that is primarily construction --
24 the construction risk that most of these investors look at,
25 this market will absolutely flow capital. We're seeing it

1 right now.

2 The biggest example is the SES or the Project
3 Astoria financing, which has a ten-year contract with ConEd;
4 that will receive financing very similar to what I've been
5 talking about. This concludes my remarks. I'm willing to
6 take questions later on.

7 MR. COLEMAN: Thanks, Jonathan. To complement
8 this discussion, we've asked Michael Thomas, Sr. Vice
9 President and Corporate Treasurer of Calpine, to give some
10 comments from the perspective of somebody who's out there
11 trying to chase that capital.

12 MR. THOMAS: Thank you very much. I appreciate
13 the opportunity to be here today and to talk about
14 reliability and must-run load market pricing and those types
15 of issues.

16 And you're probably aware, Calpine Corporation is
17 the largest independent power producer in the United States.
18 In the mid-1990s, we embarked on a vision to ultimately grow
19 the largest, highly efficient gas-fired plant development
20 program in the United States, if not the world.

21 We embarked on a vision to ultimately grow up to
22 about 70,000 megawatts in about the mid-1990s, and a lot of
23 the comments that both Frank and Jonathan are giving you and
24 that I'm about to echo here with respect to how Calpine was
25 fortunate enough to have all the stars aligned back about

1 that point in time with respect to deregulated sector that
2 had tremendous influence with the economy as a whole, free-
3 floating capital with respect to lenders willing to commit
4 cheap capital towards the development of merchant assets, as
5 well as the construction risks that you're hearing about
6 from a risk tolerance standpoint.

7 It was a period of time when infrastructure in
8 this country was primarily 20 to 30 years antiquated. All
9 the stars really were aligning for our company at that point
10 in time with respect to the vision we embarked upon.

11 At that point in time, though, we were also aware
12 that merchant cashflows were something that was very
13 volatile and very difficult to finance, not only from a
14 lender's standpoint, but certainly from an equity return
15 standpoint.

16 We looked at things a little bit differently. We
17 looked at things from a diversification standpoint and a
18 willingness to look at things such as portfolio financing
19 that had historically not been done.

20 Many of the models you had heard about, from an
21 historical standpoint, were very risk-free because of the
22 nature of the off-taking counterparty. Largely you had a
23 PPA with the utility, you had a developer that ultimately
24 went out and got an EPC contract with a strong construction
25 party and basically the risk were pretty well wrapped when

1 that project ultimately came on line and performed from a
2 performance standpoint. It basically just brought in
3 revenues and you didn't have to deal with any of the things
4 that really injected into the market, credit risk and risk
5 management volatility, things that were not part of those
6 prior structures.

7 As we moved into the merchant finance arena,
8 those risks were not really appreciated, I would say, from
9 what you hear as far as going back to the basics. The
10 basics, basically get to does cashflow have certainty? If
11 not, how risky is cashflow?

12 In my opinion, I think we entered a marketplace
13 where momentum was largely the driver towards flexibility in
14 capital and maybe decisions that allowed flexibility to be a
15 little bit too far strong. We would argue that that was
16 certainly the case for an asset that was being financed on a
17 stand-alone basis. That asset was a merchant plant standing
18 in the market alone. We felt it was very exposed, it was
19 very exposed, not only in its ability to compete with the
20 broader system, as a whole, but certainly as prices and
21 commodity prices moved, it would certainly have problems as
22 it entered the trough of the cycle.

23 Our view was, again, to look at more of the
24 portfolio approach and to basically diversify the risk
25 across multiple assets.

1 In 1998, we raised \$1.1 billion dollars for the
2 financing of nine plants across the United States. That was
3 the construction of those plants, and ultimately a mini-perm
4 takeout that gave us the ability to look toward longer-term
5 financing in the capital markets.

6 Largely, that billion dollar financing went as
7 planned, from Calpine's ability to build the plant and
8 ultimately to get those plants operational. Then we entered
9 into the market with respect to merchant realities.

10 The merchant realities, to some extent, are what
11 they are, from everything you're hearing today on struggles
12 within merchant spot spreads, the ability to generate
13 sufficient cashflow to either service debt or certainly to
14 have sufficient cashflow for equity returns.

15 We were able to pull those financings together.
16 We were able to do so with 25 commercial banks at that time.
17 Subsequent to that, we broadened our goals. We raised
18 another \$2.5 billion. We raised that, again, on a merchant
19 plant basis where construction risk was included in that.
20 Those assets will ultimately end up in the marketplace,
21 competing on a merchant basis.

22 We ended up with 45 lenders at that point in
23 time, \$2.5 billion of capital. We largely had every project
24 financed by every bank in the world willing to finance us
25 and our merchant risk.

1 Subsequent to that, as I said, we ultimately
2 performed the buildout and the ability to take most of those
3 assets to ultimately COD and the ability to compete in the
4 merchant world. The reality of what's going on in the
5 world, is exactly what you've heard from Frank and Jonathan
6 with respect to lender sensitivity.

7 Commercial banks have basically exited that
8 marketplace. We recently refinanced our CCFC \$1 billion
9 financing. We did so in the capital markets. There's not a
10 single bank that remains as a participant in that facility.

11 Largely, the billion dollars of bank capital that
12 we've recycled into the capital markets, admittedly, but
13 bank capital that's available that's not yet been redeployed
14 into the sector. So we have, similarly, our \$2.5 billion
15 CCFT-2 facility that's coming to maturity at the end of this
16 calendar year, again, 45 banks with \$2.5 billion of capital.

17 Almost certainly we're going to end up with a
18 large institutional tranche to where we direct or take out
19 that financing, 45 lenders, \$2.5 billion of bank capital
20 would be pulled out of Calpine exposure or the merchant
21 risk. In aggregate, that's \$3.5 billion of bank capital
22 that was committed as a loan to Calpine Corporation.

23 We've also seen a similar reduction in our
24 corporate facilities of about \$500 million, a reduction in
25 bank participation there. Arguably, \$4 billion of bank

1 capital that was committed to Calpine Corporation, is
2 largely not funding our corporation today or as we go
3 forward. I think that's a very important sign with respect
4 to primarily the construction of these assets going forward.

5 I think construction risk, in my mind, is the
6 biggest risk with respect to incenting a bank or a party to
7 come in to ultimately be willing to finance these assets.

8 I think what we've seen from Calpine's standpoint
9 is that once we get to an operational state, we've got
10 diversified portfolios of assets. Certainly the capital
11 markets have been the solution for us on being able to
12 refinance. Ratings have not been a material impact on our
13 ability to ultimately find economically-priced capital or
14 the ability to find a marketplace that was interested in
15 having -- you've spoken to a five- to seven-year type of
16 takeout financing.

17 We've certainly been very successful at executing
18 on that, but, that said, the next incremental merchant
19 asset, I believe, is strongly at risk with respect to where
20 their capital comes from, primarily on the up-front side of
21 the equation, both the development side of the equation, as
22 well as the construction side of the equation. Those are
23 obviously long periods of time. Plants will be developed
24 over somewhere between a three- and five-year period of
25 time. To the extent that that's supposed to fit into

1 someone's planning horizon, there's obviously a lot of
2 capital risk at stake on the up-front side, which is going
3 to be sponsor capital at stake or bank capital,
4 historically, was at stake.

5 The bank capital no longer being there, there's a
6 big hole in the market to be filled. The term loan B-
7 markets you've heard about certainly have become much more
8 robust and more accessible from Calpine's standpoint.

9 But, on the other hand, I've not seen that market
10 be willing to look at the construction state of these assets
11 to be willing to take construction risks and ultimately take
12 that asset into a COD state.

13 I think there's a big challenge on the up-front
14 side as to how you incent parties, ether sponsors or
15 lenders, to be able to look at the construction risk within
16 a market. To the extent that that market is ultimately
17 leading you to a merchant cashflow stream, the examples
18 you've heard about project financing today, are almost
19 certainly related to projects that have contracts.

20 Calpine itself has been successful in the last
21 year on raising probably about a billion dollars, plus, of
22 project finance capital. Almost all of that capital,
23 though, is related to off-take contracts that we had, that
24 had long-term PPAs, much like the old model you heard about
25 with leveraged allowances, around 80- to 90-percent

1 thresholds.

2 To that extent, unless you have a contract,
3 again, the challenge of incenting either the sponsors or the
4 lenders to step into that marketplace, I think is extremely
5 difficult in the construction phase. Certainly once an
6 asset becomes commercially operative, I think there are many
7 tools in the marketplace today to be able to finance that on
8 a longer-term take-out. Thank you.

9 MR. COLEMAN: Thanks, Michael. Do we have a
10 couple of financial questions, or do we want to move on?

11 MR. PERLMAN: I have a quick question: I heard
12 both Frank and Jonathan talk, and, I guess, Mike, a little
13 bit, about cashflow certainty with respect to the financing
14 of new infrastructure projects. Could you elaborate a
15 little more on that?

16 Are there different ways to get the cashflow
17 certainty? I heard Frank talk about a contract or something
18 that would be an equivalent of a contract from a regulatory
19 perspective. I guess we have some influence over how to set
20 some pricing structures up, but what would the financial
21 markets see as cashflow certainty-type structures that would
22 be financeable?

23 MR. THOMAS: In my mind, RMR itself is not really
24 cashflow certainty; it's more what I would just use as a
25 generic example of a check-engine light. If there is

1 something wrong, there is a signal within in this
2 marketplace that says that, economically, someone should be
3 coming in to step into that role.

4 RMR itself is a short-term subsidy or something
5 that does not have certainty from a continuing standpoint or
6 a renewal standpoint. It's not a cashflow stream that I
7 think many lenders become comfortable with. To the extent
8 that is a marker, certainly it's telling you something about
9 the marketplace as whole.

10 You do get to additional diligence levels, but I
11 don't believe that the RMR component itself is sufficient to
12 incent either a sponsor, or, ultimately a lender to be
13 willing to finance that risk at the end of the day.

14 There are other means than just contracts to
15 ultimately finance these things, but a lot of them come down
16 to more derivative types of products that are very expensive
17 to ultimately provide you largely the same answer. Could
18 you conceivably come up with a floor on your merchant spark
19 spreads that ultimately buy an insurance type of product
20 that gives you the ability to get lender certainty, that
21 would be able to serve as debt? That's basically some form
22 of a quit obligation or some form of contract-like
23 obligation, that if prices fall below a certain level,
24 certainly those structures are out there.

25 But those structures are extremely expensive.

1 The credit default derivatives you've been hearing about are
2 products that have existed, too, but they are very, very
3 expensive for parties ourselves or lenders, I would say, to
4 ultimately purchase, to be able to protect the risks.

5 So, outside of a contract, I'm struggling with
6 respect to what's the Band-Aid in between. I'm not saying a
7 contract is ultimately a ten- to 20-year contract that
8 historically existed, but certainly, a one-year uncertain
9 renewable type of incentive is not sufficient to get you
10 into a longer-term comfort level that the capital you're
11 deploying, again, three to five years up front, ultimately
12 has viability in the longer term, which is, again, the 40-
13 year-plus type asset.

14 Until you figure out a way to bridge those two
15 together, I'm not sure that RMR, in isolation, is anything
16 more than a signal that the marketplace has a need.

17 MR. NEPOLITANO: I think construction of a
18 marketplace, not physical, but the financial construction of
19 a marketplace is equally important. The contract assumes a
20 lot of things. It assumes that there is a mechanic to
21 measure something and there's a freezing of that measure in
22 terms of a price point.

23 The mechanic you need to get to measurement is
24 equally important as freezing it at a level that's economic
25 to the participants. It's not clear that in some of these

1 markets, the mechanic is transparent, and there is some
2 over-the-top activity and new type activity that is risk in
3 those markets as they develop either transmission or
4 generation.

5 As capital thinks about looking at that precipice
6 of risk, that lack of transparency with respect to the
7 measurement of the metrics, is equally a problem as freezing
8 those metrics at an equitable level.

9 MR. BALIFF: Just to say something different that
10 deals with the terms of the contract itself, I agree with my
11 comrades here that from the standpoint of how you mitigate
12 risk, kind of water seeking its easiest source, is a
13 contract with a firm capacity payment. The market is very
14 willing to take operational risk. It's even willing to take
15 construction risk. One thing it can't do, it can't keep
16 layering on these risks and say it's a financeable
17 construction with market, operational, and regulatory risks.
18 It's not going to happen.

19 So if you do have a contract, the question is,
20 how does that contract need to be, if you have these types
21 of BGS type contracts of one to three years, okay? And you
22 have significant mitigation of your construction risk,
23 either through some type of insurance, what we call a wrap,
24 a guarantee, or if some corporate will guarantee it of an
25 investment nature, then I think that is perhaps financeable.

1 There is going to be a significant amount of
2 structure around it, but it is financeable. If you get into
3 the five- to ten-year contract range, that's where the gray
4 area sits, and it really is going to be load-pocket-
5 specific. It's going to be construction-specific.

6 I would say that for the issuers at CSFB, Credit
7 Suisse-First Boston, is dealing with, the construction is,
8 by far, the more significant risk than even the market risk
9 right now for specifically the RMR. Why? Most of these
10 projects are in urban areas, and the nature of the pricing
11 has, in general, been double what the original projection
12 said.

13 So, for example, SES is counting on double what
14 it originally bought ten years. Many of the projects on the
15 gas pipeline going into New York City, those have all been
16 doubled -- the price -- just because of the nature of
17 developing infrastructure projects in urban areas, so I'd
18 say, if you can get the five-year contract, mitigate the
19 construction risks, then you'll see the capital flow.

20 MR. COLEMAN: We're going to have Frank,
21 Jonathan, and Michael, continue on with the second panel,
22 so, to the extent we need to follow up on some questions
23 there and get some more observations, we will do that.

24 I'd like to move into the second panel to keep

1 things moving here. Our first speaker on the second panel
2 actually really needs no introduction. Bill Hogan is from
3 Harvard University with a long description that I condensed
4 to purveyor of wisdom and economic justice.

5 (Laughter.)

6 MR. COLEMAN: With that introduction, Dr. Hogan?

7 MR. HOGAN: Thank you, I think.

8 (Laughter.)

9 MR. HOGAN: It's a privilege to be invited to
10 participate. I remind you that I don't speak on behalf of
11 anybody else; the comments I'm providing are just my own. I
12 have prepared some remarks, which I have submitted for the
13 record, but in the interest of time, let me try to just
14 summarize, so that we can get into the discussion later.

15 When I looked at the Order that came out, I was a
16 little taken aback by the several pages of outline
17 questions. I had first thought about trying to answer them,
18 and after awhile, I realized that for most of the questions,
19 the answer was "maybe," because, as I refer back to the
20 Chairman's introduction, it's very fact-specific.

21 So I think you have to go at the particulars to
22 get back down into that level of detail, which maybe we can
23 do later. So I thought I'd step back and just make a few
24 observations about more general issues from a market power
25 mitigation perspective to either reveal my own conclusions

1 or biases in this matter, and then I hope that will provide
2 the foundation for later discussion.

3 So I put together my top ten list of things here
4 that I would want as take-aways, and the first is that, as I
5 think is generally recognized, but just to say it, in
6 balancing imperfect markets and imperfect regulation, we
7 should lean towards markets and restructuring.

8 You want to avoid trying to go too far to
9 overregulate things to make it the perfect competitive case,
10 because I don't think we know how to do it. We probably
11 would do more harm than good.

12 Number two, market power models are useful for
13 stimulating thinking, but I don't believe the numbers just
14 yet. I spent a lot of time building and using formal models
15 of many things, including market power. I think it's a very
16 interesting topic, and I've become convinced, looking at it,
17 that it's really complicated.

18 The shorthand that we use for this, like
19 concentration indexes, or, more recently, the concept of
20 pivotal suppliers, or any of the various game theoretic
21 models and all those kind of things, I think are helpful in
22 stimulating thinking, but I wouldn't use the numbers very
23 much, because I just don't think it's possible to get past
24 the simplifications.

25 So I think the place so far that the best focus

1 is for diagnostics, is direct analysis of withholding by
2 individual generators and to look at the particulars and see
3 what you can find. That is done, for example, by David
4 Patton, Joe Bowring, and that's the great thing, I think, to
5 focus on.

6 Number 3, scarcity pricing is good, withholding
7 is bad. This is what makes all of this market power
8 mitigation hard, because you just can't look at high prices
9 and conclude that people are exercising market power. It
10 might be nothing at all like that. It might just be
11 scarcity pricing, and that's good, so you want to support
12 that and encourage it. It's the withholding you have to
13 focus on, and that's critical.

14 Number 4, electricity markets may make control in
15 real-time generation, transmission, or load in exercising
16 market power, because of the particular physical nature of
17 electricity and the way these clearing markets work, at
18 least in organized markets.

19 You can't use derivatives and forward contracts
20 to exercise market power, if you can't do something in the
21 physical market that actually occurs in real time, so that's
22 the place to focus and to look at what actually happens in
23 real time.

24 The other parts are interesting because they
25 contain incentives, but they don't actually create market

1 power, but market power exists in real time.

2 Number 5, improvements in market design under
3 competitive conditions also help address market power
4 problems. This is less of a surprising idea nowadays
5 because we've had a lot of experience. But initially, there
6 was an attempt in various parts of the country to modify the
7 market design in order to get rid of the market power
8 problem by creating a big zone or something like that.

9 We now know that that is actually
10 counterproductive. I think there's actually no tradeoff.
11 When you're considering market design issues, you can assume
12 competition, a competitive market, design the market
13 accordingly, and you won't cost yourself anything in terms
14 of market power. You probably help.

15 You won't solve the market power problem, but you
16 just don't make it worse and you don't have to worry about
17 that.

18 Number 6, monopsony, is a problem, as well as
19 monopoly. Looking for situations where people are taking
20 actions to depress prices below competitive levels is just
21 as much a problem, and we should worry about that.

22 Number 7, market power mitigation, should default
23 to the competitive outcome when market power is not present
24 or not exercised. Bid caps are much better than price caps,
25 because bid caps don't constrain competitive suppliers who

1 would bid under the bid cap. That's the kind of thinking
2 that I think we should continue.

3 Number 8, entry is crucial in long-term market
4 mitigation of market power. It's because of the lure of the
5 extra profits that people enter the marketplace to make --
6 this may come up later in the conversation. When you go
7 through the analysis, you could come to the conclusion that
8 for entry and for new generation, you could take the view
9 that you don't have to worry about it, and you don't
10 mitigate new generation that's not owned by the same
11 companies; you just let them do what they will, and that
12 provides the right kind of incentives, as long as the entry
13 barriers are level.

14 Number 9: The discipline of markets requires the
15 possibility of losing money and the exit of money losing
16 generation. It doesn't mean you don't need a market power
17 analysis for that, but exit through asset sales is quite
18 different than exit through closure, for example, and we can
19 talk about that later, but I don't think we should be
20 excessively concerned about people who are losing money.

21 Then, finally, there is Number 10, market power
22 mitigation policy needs its own exit strategy, so looking at
23 ways to design the policy and then it sort of fades away
24 over time. That is consistent, for example, with exempting
25 new generation and new investment from market power

1 mitigation, going forward.

2 And there are other things that we can consider
3 in that line. So, in conclusion, the emphasis should be on
4 good market design, expansion of market participation,
5 reducing restrictions at seams, encouraging entry and so on.

6 Local market power will continue to be necessary,
7 but it should not drive other policies at the risk of
8 defeating the basic purpose of using the discipline of the
9 market, rather than the discipline of rules. Thank you.

10 MR. COLEMAN: Thanks, Bill. We're going to
11 continue with all the speakers, and end up with a Q&A
12 session afterwards, although I know the any speaker would
13 have a number of questions generated from his or her
14 comments.

15 Next we have Michael Schnitzer, cofounder and
16 Director of NorthBridge Group, appearing today on behalf of
17 Exelon Corporation. Welcome, Michael.

18 MR. SCHNITZER: I appreciate the opportunity to
19 be here this morning and to speak after Bill Hogan. But I'm
20 going to try and describe some of the thoughts that Exelon
21 has. I have the perspective, both of a transmission
22 distribution owner with RMR issues in your service
23 territory, and also as a generation owner. The perspective
24 that they have developed, I think, is a balanced one, which,
25 with any luck, will be of benefit to the Commission as we go

1 forward.

2 I have a presentation here that I'm not going to
3 use, which some of you have a copy of. But I'm going to
4 refer to certain pages of it, but it won't be fatal if not
5 everyone has a copy of it. I'm sure we can get other copies
6 made available.

7 Let me start with the definition of what
8 reliability, must-run is, as I'm going to be describing it.
9 Basically, as Bill described it, it's a physical generating
10 asset that is needed for reliable grid operation, whether
11 it's in merit or not. It just needs to be operated for
12 whatever set of security reasons or another, and the
13 transmission fix is either infeasible in the timeframe we
14 got to real time, or it's not economic, relative to having
15 the generator there, and that's something I think we should
16 also keep in mind. Not all RMR solutions are economic to
17 fix on the transmission side. That's my definition.

18 The comment was made at the outset about the fact
19 that this is fact-specific. I think that's the case.

20 The problem is that RMR situations come in many
21 varieties. There are units that are RMR that most of the
22 time, they're in the market and economic to run, whether
23 they are RMR or not, and only occasionally do they have this
24 RMR characteristic. Coal plants, for instance, they are in
25 the money most of the hours, and there are units that are

1 not. Most of the time they run, they're RMR.

2 There are units whose RMR status is predictable
3 under normal operating conditions, and there are units where
4 that's not the case, where it's only in the hottest of
5 summers or under a previous contingency that they become
6 RMR, and those are very different.

7 And there are circumstances where the existing
8 stock of generation is adequate to meet the RMR of
9 reliability needs, and there are circumstances where load
10 growth says that they are not, and you're going to need some
11 new entry of some sort or another. That's the problem here,
12 is that you have so many of these different fact-specific
13 circumstances from which RMR situations arise.

14 For those of you who have the package, I'm just
15 going to spend a minute on page 3. The consequence of all
16 of those different fact situations is that one size does not
17 fit all.

18 A bid cap, for instance, which is used in some
19 circumstances, won't work for some non-market units whose
20 hours are not predictable and otherwise don't have any in-
21 the-money hours, no matter how high you set the cap, because
22 of infinite cap and zero hours don't generate a lot of
23 revenue.

24 Even where the caps are workable, a single
25 formula may not be workable. You have one unit which, five

1 hours a year, it's RMR and 8,000 hours a year, it's
2 generating energy profits, and variable cost plus ten
3 percent may be great for that unit.

4 You have another unit that only runs 100 hours a
5 year. They are all RMR units, and variable cost plus ten
6 percent is not going to cover the O&M and the property
7 taxes, you know. for that kind of operation. If you set bid
8 caps and replacement costs, that may encourage entry when
9 you need it, but if you don't need the entry, it may result
10 in what some people would consider to be overpayments, you
11 know, and monopoly rents to generators. That's the problem
12 we have.

13 Let me just spend a few minutes here on page 4,
14 on how we think about that, and map that into some different
15 circumstances and some different potential solutions. I'm
16 going to start with circumstances where current supply of
17 generation and transmission is adequate, which is to say we
18 don't need more generation for voltage or we don't need a
19 new transmission fix.

20 We can meet reliability criteria, as long as we
21 have the RMR controls that we need. If we have units, first
22 of all, that run predominantly in merit, and for those, the
23 bid cap is variable cost plus ten percent, I assume the
24 market monitors here will speak to, may well be a fine
25 solution.

1 But then we have units that run primarily for RMR
2 reasons and they're not in the market. They are not low-
3 priced coal units or whatever. And then we have a split.
4 Some of those are fairly predictable.

5 You know the number of hours they're going to run
6 within certain bounds that are reasonably predictable, and
7 there are some where you just don't know. It's not
8 predictable at all.

9 For the first of those, which is Category II in
10 the picture, for those of you who have it, bid caps can
11 again work, but it might not be variable cost plus ten
12 percent; it might have to be a higher bid cap.

13 For the third category, bid caps may not work at
14 all. You may need some kind of demand charge or demand
15 payment, because if someone doesn't know if they're going to
16 run one hour or 100 hours, it's pretty hard to set a bid
17 cap that will make everybody happy.

18 Then, finally, the complication, is if that
19 wasn't bad enough, is that you have some units that are
20 facing major capital additions, extraordinary kinds of
21 things where every now and again, it's a really old unit
22 and, son of a gun, I've got to rebuild the turbine and it's
23 going to cost me a bunch of money, or I've got to rewind the
24 generator or do something like that, or I've gotten an
25 environmental requirement that's going to require me to

1 spend a lot of money. And the one-year bid cap or one-year
2 demand charge contract may not be adequate to make me
3 incented to make that investment.

4 So in those circumstances, you might need to have
5 the opportunity for multi-year, longer than one year
6 arrangements of demand charges or bid caps or both.

7 Finally, we have what we refer to as the scarcity
8 situation, which is, it's great for the units that you've
9 got, but I need some additional units or I need a
10 transmission fix or I need a generation fix. And there,
11 that's a more complicated story that I'm not sure fits in
12 the timeline and the time available for my opening remarks,
13 but we can come back to that one.

14 So what that all boils down to, I think, is on
15 page 5. RTOs need an RMR menu, basically to deal with the
16 flexibility and to deal with all of these circumstances.
17 You need the ability to have a formula bid cap for the in-
18 market units, a negotiated, higher-level bid cap for those
19 Category II, predictable RMR annual contracts with demand
20 payments for those units where the hours of operation are
21 not at all predictable, multi-year contracts to deal with
22 circumstances where new investment is needed to sustain that
23 plant and avoid retirement, and then some things to deal
24 with new-entry pricing, either transmission or generation.
25 We'll wait for your questions later. Thank you very much.

1

3

1 MR. COLEMAN: Next we have Roy Shanker who has
2 some comments who is a consultant for numerous generators
3 and financial market participants.

4 Welcome, Roy.

5 MR. SHANKER: Thank you. I thank Staff and the
6 Commission.

7 As mentioned I work for generators, financial
8 participants in the market, also for some transmission
9 owners and LSEs. And, as usual, these are my own comments.

10 Following, I'm looking at it from the Staff's
11 perspective. You see me to the left of Bill and to the
12 right of Joe and David. That's probably reasonable.

13 (Laughter.)

14 MR. SHANKER: At least most of the time and I
15 think like Bill I want to take a higher view of this because
16 I think we'll get into a lot of arguments, as Mike pointed
17 out, about the specifics.

18 And Bill will go up and back in detail with that
19 as sort of a start. It's worth it to start by putting
20 everything in perspective with it to start.

21 In general we look at these kinds of RMR local
22 market power issues. The focus is always on fixing the
23 immediate problem as perceived -- it's sort of the "squeaky
24 wheel function." Then we see them, we do the patch, and
25 then we tend to forget very often in the general context the

1 objectives of what we're trying to do with the market design
2 overall.

3 Typically that's a huge mistake and I think what
4 I thought we were here to do is to try to establish a
5 competitive market structure to support efficiency and send
6 market related price signals to both generation and load
7 and, in turn, try to spur new entry, either by generation or
8 by load management or load control in meeting the market
9 demands for power.

10 Everything we do ought to come back to the test
11 of reasonableness against that objective as opposed to "did
12 I fix today's market power issue?" When we don't do that
13 we're on the road to making a lot of mistakes.

14 In that context, the first question we ought to
15 ask ourselves when considering a potential market power or
16 exercise of market power in a small area is whether or not
17 we're seeing a permanent market failure or whether we're
18 seeing some sort of a transitory point or hopefully a
19 transitory point on a path to a workable competitive
20 solution.

21 I think the way we approach mitigation of the
22 local market power and local pricing can and may be
23 different, depending on the answer to that question.

24 In the abstract you sort of want to do the same
25 things but I think when you start to make the policy calls,

1 where you start to move outside the market response, to
2 actually designing fixes, where you see a situation where
3 you say "Hah, this is not going to be solvable ever," we
4 have a basic market failure -- you're going to do things
5 differently than, you know what? We see things today.

6 We have potential for the exercise of local
7 market power but underneath all this we have workable
8 competition down the road but the reality is it's expensive
9 and we're going to have to pay something to fix the problem
10 and we're going to have to show people the prices that are
11 associated with that.

12 I think, if you make that distinction right up
13 front, you're going to follow a different path. If we find
14 that there is a transitory path to workable competition, we
15 want to emphasize compensation and full compensatory rates -
16 - I'm sorry. If we think there's not going to be workable
17 competition, then we have a market flaw.

18 I think probably the objective switches to
19 something that is more focused on full compensation and
20 efficiency may lag. I'd like to match them both but what
21 you really have to worry about is getting to an efficient
22 solution as quickly as possible.

23 Looking at only part of the problem in this
24 context and getting the seemingly right price for new
25 entrances is probably a mistake if that is all you look at

1 because what we're going to wind up doing is having a
2 problem with the incumbents and we're going to always have a
3 recurrent problem of "we can't fix that" because new entry
4 will not come on its own.

5 Also, if we put together patchwork solutions in
6 the market failure case I think we're also going to wind up
7 with solutions that tend to have a lot of properties that
8 look like the exercise of monopoly power.

9 We can talk a little bit about that later.

10 Alternatively, if we think there's a structural -
11 - no structural bar to entry or it's a low entry barrier,
12 then the focus would be on understanding why the current
13 situation isn't resulting in workable competition. Why is
14 there the potential for the exercise of market power that
15 exists now and do just what Bill was saying, develop pricing
16 and mitigation strategies with the intent of moving towards
17 a workably competitive solution?

18 You look at this as a transition point, not as an
19 end-point. It doesn't mean no mitigation of market power
20 exists, but it means mitigation coupled with as accurate a
21 pricing as possible to allow market recovery of cost by
22 participants both generation and transmission.

23 The basic pricing elements here have to be
24 targeted on short run pricing signals that reflect
25 locational energy scarcity and locational installed

1 capacity, if necessary.

2 The main elements here, as usual, are getting the
3 prices right first, then worrying about the mitigation.

4 If we have the right price incentives for
5 everybody's behavior, the mitigation almost becomes obvious.

6 In fact, the distinctions, if you work through
7 the details between some of the arguments that exist between
8 PJM and New York in mitigation strategies almost disappear.

9 If we start to see scarcity pricing like demand
10 reserve curves, locational ICAP, all of the typical pick-up
11 everything that should be on the table for the correct short
12 run price signals -- when you do that it becomes almost
13 obvious how to mitigate because if you do things kind of
14 cost plus mitigation or you do things like impacting fresh
15 hold mitigation in the right scarcity pricing scenario
16 you're going to get the same answer, there's not going to be
17 a differenc.

18 A quick example, and I probably won't get to do
19 much of it, given where the time is going, is to put those
20 principles to work in the context of something that's
21 actually happening and I think probably what you'll hear
22 more about tomorrow is the PMJ example and I think what you
23 need to look at in a situation that comes about -- they're
24 assuming that there is a workably competitive solution -- is
25 to go back to the basic principles and say "here is a

1 situation in PJM that's predicated on physical scarcity."

2 At least the auction proposal that's coming up
3 and the concern that either retirement or lack of new entry
4 will lead to an OMR reliability issue because incumbency
5 will not be earning sufficient revenues to stay in the
6 market and, if you go back to the first principles that
7 we're taling about here, and say "we're trying to send the
8 right price signals," then you scratch your head and say
9 "we're trying to send the right price signals" but somebody
10 who is absolutely needed for reliability isn't earning
11 sufficient returns to stay in the market.

12 What yu ought to do in a situation like that is
13 say, "Hmm, I think there's workable competition down the
14 road. I think there's new entry." It may be expensive in
15 that situation but how is it that a unit can be vital and at
16 the same time not get any capacity revenues, which would be
17 the case in today's world and, two, possibly not getting
18 sufficient operating margins to stay in the market under
19 cost plus ten pricing.

20 The answer ought to come back reasonably quickly.
21 The first thing we ought to do where we think we have a
22 transition to workable competition is to get those prices
23 right. That means to go for scarcity pricing and to look
24 for locational reserves -- one option, as Bill was talking
25 about, locational installed capacity payments or other

1 pricing remedies -- and see if they resolve the problem as a
2 transitional point towards a workable competitive solution,
3 as opposed to immediately going to solutions on RMR type
4 contracts that are probably more consistent than a permanent
5 market failure.

6 MR. COLEMAN: I know we'll be getting into that a
7 lot tomorrow and I think the conversation and the Q&A will
8 follow up on that.

9 Next we have David Patton, President of Potomac
10 Economics, and a market advisor to a number of organized
11 markets here in the U.S.

12 MR. PATTON: I appreciate the opportunity to
13 speak today. Like the others, these comments only represent
14 my own views, although I'm optimistic that my clients might
15 agree with some of them.

16 (Laughter.)

17 MR. PATTON: And probably not -- I'm going to try
18 to move quickly. My goal is going to be to try to lay out a
19 framework for thinking about some of these issues because I
20 think sometimes we get confused and try to identify what the
21 real objectives are.

22 What we're trying to balance is two objectives.
23 The first is establishing efficient economic signals in load
24 pockets.

25 The second is mitigating excessive market power

1 that often exists in a load pocket.

2 Most of my comments are going to be focused on
3 the first area. I probably won't have time to say much about
4 the second, although suffice it to say that I agree with
5 Bill, that resource-specific offer caps, I think, are
6 clearly the best solution because they allow the market to
7 continue to operate and are the least disruptive.

8 But we can talk about that more in the follow up
9 discussion so I'm going to focus on the economic signal,
10 which I think is really the key.

11 The first thing I would say is it's critical to
12 recognize that new investment is not always necessary in the
13 load pocket. We often hear things or talk and make
14 statements such as "we need to make sure that signals are
15 sent that we need investment in a load pocket."

16 That's not actually true. What we want is an
17 efficient economic signal so that when capacity is needed in
18 the load pocket, we're sending that signal but, when there's
19 a surplus in the pocket, we're not sending that signal.

20 Even when there's a surplus you can have
21 significant market power problems. You can have a surplus
22 of capacity in the load pocket but it's all earned by one
23 player.

24 Secondly, I would say, moving down into the
25 economic signals, where does the source of value come for

1 resources in load pockets? It comes from two primary
2 things. One is the ability to relieve transmission
3 constraints, which should be reflected in the locational
4 marginal prices in an LMP market.

5 But second is that they provide capacity value in
6 the load pocket to maintain reliability.

7 I would say all but one of the centralized
8 markets have no market mechanism to account for this value.
9 What happens is we get into a situation where the RTO says
10 "I need the capacity." The owner says "It's not economic to
11 keep it in operation" so you default to an RMR contract.

12 What that's a symptom of is "is the fact that the
13 market isn't complete and doesn't reflect that value?" The
14 exception I'm talking about is New York City where there's a
15 locational capacity requirement so there's a means of
16 pricing it.

17 What I'm going to try to lay out for you is five
18 alternative sources to price that second source of value for
19 resources or compensating generators in load pockets.
20 Number one is location-specific operating reserve
21 requirements. Nearly all these markets that have
22 recognizable load pockets have a capacity requirement that
23 they use on a daily basis to commit generation.

24 Usually they call that a "local reliability
25 requirement." What that means is that a non-market

1 requirement that the operators have to meet but there's no
2 market equivalent of it so there's no pricing of that
3 constraint in the market.

4 On establishing location-specific operating
5 reserve requirements you can do effective shortage pricing
6 in that area so that, when you can't meet that requirement,
7 you reflect the economic value of those reserves in the
8 energy price in that area that's being proposed on a broader
9 basis in New York right now.

10 The drawback is that, if there's been a history
11 of insufficient investment in transmission and generation,
12 putting this in place can create an overwhelming signal that
13 would be difficult to implement in one step.

14 So that's the primary drawback.

15 The second alternative is the locational capacity
16 market, which you can think of as a proxy for those short
17 term capacity requirements.

18 The longer term capacity requirement that exists
19 in New York City today -- it's a signal that's not likely to
20 be nearly as volatile and can be phased in in an market
21 where none of these requirements exist.

22 The third alternative would be an RTO auction for
23 new capacity in the load pockets. An example of that is
24 what PJM is proposing. It's very similar to the locational
25 capacity requirement except that it's a more discrete

1 process and it establishes a longer term obligation with the
2 new supplier.

3 The important thing is that the clearing price
4 from that process needs to be paid to the existing suppliers
5 in the pocket in order to set a market clearing price for
6 the capacity in that area.

7 Number four, if you don't do the first three and
8 we don't do the first three -- with one exception, is
9 loosened market power mitigation and an example of that is
10 "push" provisions in New England -- when we get into a
11 debate about how high we should set offer caps when we
12 mitigate so that we preserve signals, what we're really
13 debating is this fourth alternative and what we've
14 implicitly done is decide we're not going to do the first
15 three, which I think is a mistake, because if you do the
16 first three so that you're pricing on a market basis, the
17 value of capacity in the load pocket -- then it
18 substantially reduces the concern that your mitigation is
19 too aggressive and is going to prevent price signals in the
20 load pocket from being efficient.

21 The problem with this approach is it's less
22 reliable than the prior approaches because it relies on the
23 exercise of market power to generate the signals so you can
24 have a situation where you have concentrated supply in a
25 load pocket which leads to excessive signals when there's a

1 surplus or what we've seen in some of the "push" results is
2 that you can have load pockets where the supply is
3 sufficiently deconcentrated that you need investment but
4 nobody has enough market power to generate the signal even
5 when you loosen the mitigation.

6 Lastly, the worst alternative is unit-specific
7 RMR contracts, but the default of everything else fails --
8 is my least favorite because it sets the least transparent
9 signal. It doesn't represent a market clearing price in any
10 sense and I think, as some of the finance community
11 commented, it's least likely to generate new investment
12 because of relatively short term commitments for the
13 generation in that pocket.

14 I'd be happy to talk about my views on mitigating
15 local market power in the discussin phase.

16 MR. COLEMAN: Thank you, David.

17 Next we have Joe Bowring, PJM market monitor.
18 Welcome, Joe.

19 MR. BOWRING: Thanks for the opportunity to be
20 here to day.

21 I agree with the general overall comments of
22 David and Bill who preceeded me. Let me try to add
23 something to the discussino.

24 First of all, the context for all this is broadly
25 competitive wholesale markets. Within that context, local

1 market power situations are really an aberation as you know
2 from the data we've made public about PJM in particular,
3 even though cost capping gets a lot of attention that does
4 not really occur very frequently.

5 We don't really have many load pockets where it
6 occurs. Nonetheless, it has to be addressed. The goal is
7 to ensure competitive outcomes in the presence of local
8 market power and, ultimately, as a number of our speakers
9 today have suggested, to reduce local market power, and
10 finally, the need for mitigation.

11 It's also useful to bear in mind that the impacts
12 of local market power can be quite significant.

13 In the recent Delmarva proceeding before the
14 Commission there was some discussion whether or not there
15 was market power.

16 Yell at me. I'm not supposed to talk about this,
17 David -- there was some argument that market power existed.
18 There was significant congestion.

19 Nonetheless I don't believe there was local
20 market power exercized. If there had been, the levels of
21 congestion could have been from five to ten times higher
22 than they were in fact.

23 Local market power is, simply put, the ability of
24 a generation owner to raise the price in an area above the
25 competitive level.

1 The competitive level is well-defined. We may
2 quibble about whether it's the right mitigation level but
3 the competitive level is the short run marginal cost.

4 This is not a hypothetical or theoretical point.
5 This is the way that the generators actually offer their
6 power in the broader PJM market.

7 In many load pockets we have more diversity of
8 ownership and that's exactly where we'd expect to see it.
9 Local market power was created, as others have suggested, as
10 you know, as a result of transmission constraints.

11 Those transmission constraints can be either
12 temporary or longer term and they effectively create
13 monopoly power at the margin for one or more owners of
14 generation in the area defined by the transmission
15 constraint.

16 So far it's worth noting, as others have, that
17 there are two broad categories of mitigation we have to
18 think about. One is in situations where there is scarcity
19 and the other is in situations where there is not scarcity.

20 In situations where there is not scarcity,
21 clearly the approach -- I believe the approach we have taken
22 at PJM makes a lot of sense -- and that is, simply, the
23 higher of the market price or cost plus 10 percent.

24 When that's criticized, frequently the result and
25 potential impacts on revenues are discussed but, in actual

1 fact, when you look at the details, the net revenues of
2 those units that are cost capped do not vary significantly,
3 contrary to what one might expect -- do not vary
4 significantly by the percent of hours cost-capped.

5 Par of the reason -- or really, the only reason -
6 - that net revenue has been an issue for units in PJM
7 including those in load pockets has not been local market
8 power mitigation but has been broad market conditions.

9 As one understands that prices in the broader
10 energy markets, as well as capacity markets have been
11 depressed compared to historical levels, and also compressed
12 compared to expectations, wherein a low period of pricing in
13 everyone's net revenues, are down -- cost-capped units are
14 not disproportionately effected.

15 In fact, it's a broader market issue and it's
16 very important to keep that in mind when designing local
17 market power mitigation in order not to overreact to the
18 broader market results.

19 The second broad category, of course, is when
20 scarcity exists, local market power can and does exist for
21 that scarcity. In fact, in general in PJM, load pockets do
22 not have scarcity. Generally there's more than enough
23 generation in the load pocket to serve the load and that of
24 transmission import capability.

25 So it's not a question of scarcity. In that

1 case, scarcity pricing clearly of any kind doesn't make
2 sense.

3 Nonetheless, as we pointed out repeatedly, and
4 everyone understands that situations of scarcity do have to
5 be addressed, David and Bill and others talked about ways to
6 do that. "Scarcity" again I'm defining as 'the inability of
7 existing generation to meet load reliability in a load
8 pocket."

9 It's an engineering definition but I think that
10 it also works for economic purposes as well here. We need
11 to create market based incentives to resolve scarcity issues
12 and what we propose and will talk about in detail tomorrow
13 is an auction.

14 But the intent is to have, as I said, a market
15 based mechanism, not an administrative mechanism.

16 Unfortunately scarcity pricing, while it sounds
17 like a market based mechanism in a load pocket with one or
18 two generators ultimately boils down to an administrative
19 mechanism -- someone has to decide what that price is going
20 to be. It doesn't fall onto the market particularly when
21 you have no demand side.

22 While I agree, I think, with all the speakers
23 that the market based mechanisms are appropriate, we have to
24 be very careful to get past what appears to be superficially
25 a market based mechanism to ensure that we literally are

1 having a market based mechanism.

2 An essential component of the option we proposed
3 is that all forms of solutions to load pockets get to
4 compete against one another heads up. That is, transmission
5 generation as well as DSM. All three of those are ways of
6 addressing load pockets. All three should be considered and
7 should be considered in a market context so that the least
8 cost alternative as defined by the market gets to solve the
9 problem.

10 Our MR contracts might well be a last resort in
11 situations as have been defined where local market power is
12 a long term systemic issue and there's never likely to be a
13 market solution and there's never likely to be a
14 transmission solution and there's really no alternative.

15 But it clearly is a last and, in my view, poor
16 solution. Thank you.

17 MR. COLEMAN: Thanks, Joe.

18 Next we have Roy Thilly, Chief Executive Officer
19 of Wisconsin Public Power, Inc.

20 Welcome, Roy.

21 MR. THILLY: I'm going to swim a little bit
22 upstream a little bit this morning and suggest that LMP,
23 with significant or high mitigation ceilings is not the
24 right approach to what ought to be the objective, which is
25 to get the infrastructure in place and constructed so all

1 customers will benefit from competitive wholesale markets.

2 I come from the perspective of being in one of
3 the worst load pockets in the country. We are the ones who
4 would pay the scarcity price if the system works and will
5 pay it for an extended period of time because the fixes are
6 not quick.

7 If in fact the incentives don't work as intended,
8 we'll continue to pay it while others will go back to the
9 drawing boards and look at an interesting problem of what to
10 do next.

11 I would urge the Commission to be careful to
12 recognize that there will be gaming, particularly of complex
13 mitigation arrangements. The theory is elegant but the
14 facts on the ground are messy.

15 I think there are two key questions that were
16 asked. One is, is there a single policy that fits for all
17 markets? My answer to that is, "no there's not."

18 The facts are different. The economic drivers
19 are very different. An obligation to serve states in retail
20 access environments and the entry barriers are very
21 different in the different places.

22 If you don't take account of that in the design
23 the design will fail.

24 How important is infrastructure to solving
25 the load pocket problem? Transmission infrastructure is

1 essential for solving the problem. If you get a robust
2 transmission system, market design is easy and gaming is
3 very hard. That should be the objective. The objective
4 should be generation to generation competition. that's what
5 will benefit customres.

6 The idea of having transmission compete against
7 generation is I think a false solution that will result in a
8 significant dampening of generation competition.

9 Transmission is very, very hard to build and
10 needs to be addressed on its own merits. I have a concern
11 that some think there is a legitimate interest in congestion
12 that needs to be protected. FTR values, the value of
13 constructing a generation load pocket -- there maybe an
14 interest but it's not an interest that should be protected
15 or fostered by market design.

16 I fear that high mitigation ceilings will create
17 a segment, probably a powerful segment with an interest in
18 maintaining congestion. It will certainly dictate bidding
19 strategies over a mix of generation in annd outside of the
20 load pocket to maximize profit but not necessarily to
21 stimulate entry.

22 And I fear that it will create a whole new class
23 of environmentalists concerned about the biodiversity of new
24 transmission right of way.

25 You have to look at who can build -- one of the

1 big problems we have is that the RTOs theoretically have the
2 ability to compel construction but I think that's extremely
3 difficult. I haven't seen it done in a large owner.
4 Benefitting from congestion can create many, many roadblocks
5 in the state process to getting transmission built and built
6 promptly.

7

8

1 What are the "must-haves?" I think you have to
2 look at "must run" policy in light of the broader market
3 design. I'd say the "must-haves" are, one, a system that
4 focuses specifically on getting transmission constructed for
5 load pockets. There are a number of steps that can be taken
6 there that I can elaborate on.

7 Resource adequacy requirements are essential.
8 Starting up with a market without resource adequacy and
9 depending upon spot energy prices to cover fixed costs is a
10 disaster from the load pocket perspective.

11 I think we heard it also is not finance-able. We
12 need certainty, transparency and the ability to cover fixed
13 costs, and a capacity market must run loosened arrangements
14 and so is very problematic from a load pocket perspective.

15 We need the capacity market. Then we should
16 price "must runs" at marginal plus a reasonable profit, 10
17 percent profit -- unless you have true scarcity. The
18 problem is differentiating between scarcity and withholding.

19 Most of the schemes don't really try to do that.
20 They just set a high ceiling and mitigate without
21 determining. I would say true scarcity exists if you have
22 to dip into operating reserves and you can't replenish them
23 within the short period of time you're required to do so by
24 the reliability rules.

25 Also, you have to have an accurate assessment of

1 the barriers to entry. They will be different in different
2 places and the barriers to entry where I live are very high.

3 We have obligations to serve the State. We do
4 not have any IPPs that control their own generation. It's
5 all under contract to the big players and there are no IPPs
6 that are going to build on speculation of energy prices.

7 That gets to the point that you need consistency
8 with the retail model that you're operating in because the
9 retail model is going to provide a lot of the drivers that
10 influence behavior and if you have an inconsistent wholesale
11 model on top of it, you're asking for trouble.

12 Finally, just a comment on the incentives -- as I
13 look at it where I live, scarcity pricing incentives take at
14 least five years to solve the infrastructure problem.

15 In the mean time, what we see happening is
16 industry shifting production elsewhere out of state -- paper
17 companies shutting down paper machines and maybe won't have
18 to build when they get down to the building cycle.

19 But that's not the kind of incentive that makes
20 sense from our State's point of view.

21 Thank you.

22 MR. COLEMAN: Thank you, Roy.

23 Our last speaker on this morning's panel is Abram
24 Klein from Edison Mission Marketing and Trade.

25 Welcome, Abram.

1 MR. KLEIN: Thank you very much. I'm very glad
2 to be here.

3 I am director of Northeast Trading for Edison
4 Mission Marketing and, trading as a market participant, I
5 see how some of these market design issues actually play out
6 in terms of market performance on a day to day basis.

7 I'm also an economist that has worked on local
8 market power issues currently and in a previous life.

9 What I want to do is focus my comments on two
10 main areas, the first is to look at the local market power
11 problem in a broader overall market design context and look
12 at market performance in that context.

13 If you have a generator that's inside a load
14 pocket that's needed for reliability and it's not making
15 enough money, why is that?

16 Well, it could be that the prices are not high
17 enough inside the load pocket.

18 It also could be that the prices are not at
19 competitive levels in the market more broadly. I think you
20 have to do that assessment in order to determine what the
21 proper policy prescription is.

22 I think that sort of approach, looking at the
23 broader market design, is consistent with the standard
24 market design.

25 The second concern which I will try to address

1 later if there's time is what I'd refer to as "mitigation
2 creep" and that is the Commission is given sort of a broad
3 based authority to the market monitoring unit to address it
4 but it's not very narrowly defined and it can be used in
5 ways that I think with not necessarily the intention but it
6 might be appropriate to prescribe a little bit more what
7 should occur.

8 In terms of the broader policy context, lets look
9 at market performance in Northeast ISOs. How are these
10 markets doing?

11 Well, if we look at the period from 2000 to 2002,
12 each of the Northeast ISOs had very tight reserve margins on
13 an annual basis. During 2001 and 2002, each of the
14 Northeast ISOs had multiple days of real scarcity and very
15 many high demand days, particularly in 2002.

16 One would think that spot energy prices in a
17 workably competitive market in that environment should have
18 actually been above the cost of entry and perhaps
19 significantly above the cost of entry -- at least not just
20 at the cost of entry.

21 The reason for that is basically two reasons.
22 The first is that we know the entrant is going to expect the
23 commodity market to be somewhat cyclical and go through a
24 "bust" cycle so the prices need to be higher during the
25 period when demand is very tight -- or the capacity margin

1 is tight and the demand is extreme, to make up for those
2 later, lower periods.

3 If you don't have prices that are at entry cost
4 when demand is extreme and the capacity margin is tight,
5 that certainly bodes poorly for the overall market
6 structure. That says that the market structure is flawed
7 and part of the result would be the loss of investor
8 confidence in the energy supply business.

9 So in looking at how the markets actually
10 performed -- I provided in my prepared comments some tables
11 that look at it, but certainly my analysis of it is no
12 different from the ones provided by each of the ISOs in
13 their states in the market reports looking at 2001 - 2002.

14 That is, the actual market prices were
15 significantly below the cost of entry even when entry was
16 needed during those periods.

17 What I'd like to say is that the response to the
18 current market structure flaw has been different between the
19 different ISOs. In New York we have had a set of
20 initiatives and reforms aimed at addressing scarcity pricing
21 and addressing market flaws in the reserve adequacy market.

22 The installed reserve markets -- those have taken
23 place in 2003 and I think those are scarcity pricing and
24 energy demand curve end reserves. There's also an
25 interregional effort to look at a longer term market for

1 reserve adequacy as well in the Northeast. We'll see how
2 that goes.

3 But those are all potential solutions to the
4 broader market problem. In PJM we still have the same
5 market structure -- essentially that we had during 2000 and
6 2002 so, if we look at the "must run" problem in that
7 specific context, you really need to fix the broader market
8 first there and deal with some of these issues first before
9 just addressing the load pocket problem or scarcity
10 problems.

11 If you only look at the load pockets essentially
12 what you have is a situation where you're price
13 discriminating so that capacity inside the load pocket
14 actually gets paid a higher price even though what you
15 really need is higher prices in the market more broadly.

16 Let me just briefly address the other issue,
17 which is "mitigation creep."

18 My concern here is that some of the
19 authorizations to do cost capping, say in PJM, were
20 developed in 1997 before we had any experience with the
21 market. Those authorizations say that any time that there
22 is a transmission constraint anywhere in the pool, there can
23 be cost capping unless it's one of the three major
24 interfaces.

25 I think that was appropriate at the time when we

1 didn't have any experience with the market. But a lot has
2 changed since 1997 and I think that we ought to be looking
3 at revisiting where that authority lies.

4 One of our concerns is the market monitoring unit
5 in PJM would like to use the authorization to mitigate local
6 market power to, under certain conditions, declare the whole
7 Northern Illinois area as a load pocket.

8 Once Com Ed is integrated int PJM under certain
9 circumstances, Northern Illinois is a bigger area than New
10 England. There could be a situation where you have no
11 transmission constraints within Northern Illinois or into
12 Northern Illinois from the surrounding regions.

13 Yet that area would be declared a load pocket
14 simply because there was a contractual constraint on the
15 contract path from PJM into Northern Illinois -- so I think
16 that it would be appropriate to look back basically at the
17 overall authorization to do mitigation in some of these
18 circumstances and fine focus on where the load pockets are
19 and I think we know where they are generally in PJM and just
20 narrowly address local market power mitigation to areas
21 where there really are local market power problems.

22 Thank you.

23 MR. COLEMAN: Thank you.

24 I know I had promised folks at the outset that my
25 time management would be good and we'd be taking a break

1 around now. We happen to have the Chairman and all the
2 Commissioners here and we haven't gotten any questions.

3 So, unless there is a problem, I would like to
4 start off with some questions and, with all due respect to
5 the Court Reporter who may need a break, try and keep this
6 conversation going because this is really the crux of what
7 we wanted to get to this morning.

8 So if we can just go with that alternative with
9 some questions from Staff and/or if the Commissioners have
10 anything to ask of the panelists, please jump in, too.

11 MR. PERLMAN: I have a question. I heard Mr.
12 Thilly talk about a preference for infrastructure to help
13 solve some of the load pocket issues. Within the scope of
14 the solutions that each of you talked about, infrastructure
15 was a component.

16 There's a point in time, I guess, in Mr.
17 Bowring's proposal where you trigger an infrastructural
18 approach on some sort of long term engineering scarcity
19 analysis.

20 I guess my question is to each of you, 'how
21 should the Commission take into consideration the idea of a
22 policy that will incent infrastructure to remove the load
23 pocket issues and how can it consider that in the overall
24 way that it structures the way it approaches this issue?'

25 I'm not being articulate but I guess it's a

1 difficult thing for me to say when you reach the point where
2 you need to flip into that -- how does the Commission have
3 that trigger set, if at all?

4 Roy?

5 MR. SHANKER: Two things. The more transparent
6 solution in the comments that most of us offered to day was
7 'get the prices right' and the generation alternatives
8 should be there.

9 I'm a little concerned with the perception that
10 somehow transmission is differentiated absent a showing of
11 market failure. That's why it's important to go back to
12 that first criterion. The fact that something is more
13 expensive as a solution is not de facto a purpose to
14 mitigate or to price discriminate -- or to exert monopsony
15 power.

16 If the alternatives are between expensive
17 generation and expensive transmission and there aren't
18 barriers it's telling you something. It's more expensive to
19 serve load in these areas and at the margin -- that's the
20 price signal we want to send.

21 A lot of this discussion forgets the fact that
22 the existing resources that are relatively adequate to meet
23 the existing loads as we are going forward and people have
24 an opportunity to hedge themselves against those -- so what
25 we're seeing is not some sort of rampant run up of prices

1 for everybody, we're seeing an unhedged portion of load,
2 people seeing the marginal cost of entry for transmission or
3 generation.

4 Given that, there is a concern about how do you
5 mitigate properly? That's always the second response after
6 you get the prices right. We shouldn't run hiding from high
7 prices if they're the right signal. This is Bill's -- you
8 know, scarcity is good. Market power is bad.

9 As long as that signal is there coupled with the
10 absence of barriers to entry, we should be happier with
11 higher prices in those locations and the entry will be happy
12 with higher prices.

13 MR. THILLY: We're not happy with higher prices
14 in our location.

15 (Laughter.)

16 MR. THILLY: And it's not surprising that
17 generators don't want a robust transmission system because
18 it forces competition right down to the wire.

19 The trigger -- we're already there. Look at the
20 statistics on transmission investment in this country over
21 the last 15 years -- they're pathetic.

22 So I think the question is, 'how do we get it
23 done?' If you step back, where is it getting done?

24 Well, one place I think we're somewhat successful
25 is because we've had divestiture in Wisconsin. We have a

1 company that can build transmission only that cannot be
2 involved in generation and the only way it grows its
3 business is by construction.

4 It's got a 10 year budget of \$2.8 billion,
5 quadrupling the rate base, far in excess of what was planned
6 when it was owned by the individual vertically integrated
7 systems.

8 Performance based rate making? We ought to
9 reward those who have robust systems and take actions
10 promptly to relieve congestion. We ought to penalize
11 transmission owners who don't relieve congestion, focus it
12 specifically on transmission.

13 We should avoid artificial barriers like arguing
14 endlessly over whether a facility is for reliability or
15 economics. The fact of the matter is, transmission
16 construction to create a robust system benefits everybody in
17 the load pocket. Let's get it done and move on.

18 There's a proposal that has been filed by
19 American Transmission Company to address the real risks of
20 construction, which is pre-certification costs over extended
21 periods citing risk and construction work in progress when
22 you have a major construction program. That will eventually
23 lower the cost of capital and lower the cost to customers.

24 We need to find a way to enforce the obligation
25 to build through RTOs and to get teeth into the planning and

1 building process.

2 We need to create a system where people can get
3 long term transmission rights from new base load resources,
4 which is essential. All these incentives simply incent
5 peakers which will result in a system that is suboptimum.

6 Finally, the Commission has the authority to take
7 market based pricing away from transmission owners that
8 don't solve constraints. I think there's significant teeth
9 in that possibility.

10 MR. O'NEILL: Can I ask you a question? Is the
11 reason why you're upset about the possibility of high prices
12 in your load pocket because you're short in the market?

13 MR. THILLY: We're primarily a purchaser and
14 being a purchaser in a load pocket --

15 MR. O'NEILL: So you are short in the market --
16 why aren't you long in the market?

17 MR. THILLY: I should say we have -- everybody
18 has 18 percent reserves. All the fixed costs are covered in
19 my market because of regulation.

20 But the exposure, first of all -- the \$64,000
21 question is whether we're going to be covered by FTRs in
22 this market. If you're not, you're exposed. We certainly
23 don't have a guarantee that we're going to be covered by
24 FTRs and no way to hedge new long term resources.

25 MR. O'NEILL: So your exposure is whether or not

1 you get covered by FTRs?

2 MR. THILLY: That is a big part of it.

3 MR. SINGH: Also, you suggested that transmission
4 is a better solution but if you have a load pocket where the
5 constraint binding only a few hours a year, you're not
6 suggesting we should build transmission even in the old days
7 when there was a trade off between generation and
8 transmission?

9 MR. THILLY: I'm talking about areas that are
10 significantly constrained.

11 MR. O'NEILL: We solved the problem of incentives
12 I think in the gas area by basically contracting out all the
13 FTRs, if you will, to the non-pipeline companies, to the
14 LSEs. That way they couldn't benefit from any of the
15 congestion rents that may have occurred on their pipeline
16 system and certainly had then all the natural incentives to
17 expand the system.

18 Would that work in electricity?

19 MR. THILLY: It might. I thought about whether
20 you ought to require somebody who's benefitting from
21 scarcity pricing and has generation on both sides and owns
22 transmission -- to divest some of their FTRs so they don't
23 have the benefit of those FTRs.

24 MR. O'NEILL: In gas we basically separated the
25 LSEs from the transmission owners.

1 MR. THILLY: In my market, of course, we've
2 divested transmission and everybody's unbundled. But what
3 you have is very significant concentration on ownership and
4 control of the generation and concentration that is
5 increasing -- not decreasing.

6 MR. O'NEILL: Do you see this as a temporal
7 problem now that you have independent transmission?

8 MR. THILLY: I think if you give us five years
9 and we've constructed major new coal units of which the
10 fixed cost recovery is guaranteed for the life of the units
11 by state regulation, it's been put in place so there isn't
12 any risk -- and we get the build out on transmission that is
13 in the process of going through the certification process,
14 we'll have major steps and I won't have the same concerns I
15 have today.

16 MR. KLEIN: Could I also respond? I work for a
17 generation owner that's actually near that load pocket.
18 We're in sort of a glut area and we'd like to get into that
19 load pocket.

20 We actually, as generation owners, would like to
21 see some transmission built but we also view it as important
22 to do it in a way that first has the prices right.

23 I don't know how you would measure a performance
24 based rate on how well the transmission company reduced
25 congestion if you didn't know what the congestion was in the

1 first place.

2 Certainly the experience in LMP markets in PJM
3 with Delmarva is sometimes they're actually very low cost
4 solutions to relieving transmission constraints, like
5 upgrading key bottlenecks and transformers that are the key
6 bottlenecks on the grid that actually don't require multi-
7 billion dollar investment programs by the utilities.

8 So it's quite possible that you actually go to
9 LMP in Wisconsin and you don't get such high prices at all
10 on -- certainly, I don't think that it's so much higher
11 necessarily once they go to LMP than the areas outside.

12 There will be transmission congestion during
13 certain times but I don't think it's as persistent.

14 MR. O'NEILL: Are you saying there are cheap
15 fixes?

16 MR. KLEIN: There may be.

17 MR. PATTON: One quick point that I think is
18 important to recognize is that we all support the
19 infrastructure solution. I think virtually every economist
20 that talks about mitigation says structural mitigation is
21 the most effective.

22 That's building transmission and generation,
23 decreasing concentration. I think the critical question is
24 'how much?' If you think about investment in
25 infrastructure, how much of that investment can be private

1 and how much has to be either compelled on the regulator
2 venue or more recently thinking about having the RTO
3 essentially being a counterparty for a contract to build
4 something on behalf of the load in there.

5 The real question is, 'how much of the investment
6 has to be put on this side?'

7 The first preference of just about everyone would
8 be to say, "where you can set up a market that sends an
9 efficient signal, that becomes the basis for the long term
10 private contracts that can be used to finance investment."

11 That's superior, to make the deliberate choice
12 for certain other types of investment that can't happen and
13 then to try to employ logic to try to employ a criterion
14 when making those investment decisions that is consistent
15 with how a private investor would approach it -- in other
16 words, 'don't invest in non-economic projects,' just because
17 you have somebody you can pass the costs to.

18 MR. BOWRING: Just to add very briefly, the
19 Commission already has in place for PJM and I assume
20 elsewhere a policy of how to trigger transmission investment
21 to address congestion. Our point in the auction, and I
22 think it's consistent with what David just said is that we
23 have to make sure we have a market evaluation heads up on
24 generation against transmission against demand side
25 resources and in fact a significant incentive to do the

1 auction is to ensure that we don't build more expensive
2 transmission than the generation alternative would be.

3 It may well be we're building -- even Roy's high-
4 price generation would be cheaper than building
5 transmission. We need a systematic way to ensure the market
6 gets evaluated.

7 MR. COLEMAN: That's really my question. I
8 understand what both of you are saying but if we were to
9 rely on scarcity pricing, for example, and somebody built
10 enough generation to relieve the scarcity, would they still
11 receive scarcity pricing going forward now that the
12 constraint is gone and, if they wouldn't, why would they
13 build it? Because the price point that they're building
14 towards has now been eliminated.

15 So we have to have a regulatory policy that, like
16 you said, puts in place the appropriate incentives to meet
17 the goals and that's something that your feedback would be
18 very helpful for.

19 MR. SHANKER: There's something of a "Catch-22"
20 involved in all this when you start to say, "Give me a
21 chance to build enough, put enough transmission in and
22 enough generation in to suppress prices -- then I don't have
23 to worry about this."

24 That shouldn't be the goal because then, what
25 we're doing is assuring that there's never going to be a

1 world that anybody under private investment is going to put
2 a nickel up to the extent that they invest other than on a
3 bilateral. They have no confidence that the market won't
4 undercut them by some sort of a socialized investment.

5 It's too simple.

6 Again, this is a transitory problem and Roy's
7 concern is that there are load pockets that cannot be
8 resolved at any cost and only by this intervention we are
9 setting ourselves up for the need for a permanent solution
10 to solve this problem.

11 Benefit is only some sort of transitory issue of
12 people getting over the threshold of pain. Then maybe it
13 isn't him. Maybe it's not his customers. But the question
14 is, who pays?

15 Is it somebody who located resources outside the
16 load pocket because it's cheaper to build and was
17 essentially getting free or socialized redispatch for a long
18 period of time without paying for it and is now being
19 confronted with those costs?

20 Is it somebody who's going to enter into a
21 bilateral to sustain it?

22 Is it somebody who found it's cheaper to build
23 other resources, and we saw this in the Delmarva Peninsula -
24 - somebody had six years to build -- they built. They built
25 in the wrong place. They said they did it because it was

1 cheaper to build where they wanted to build rather than
2 where it would relieve congestion.

3 These are complicated questions that go back to
4 is it a persistent failure or simply somebody trying to
5 avoid higher costs or reassign those costs through
6 regulatory mechanisms to other people?

7 When you facilitate the latter you destroy the
8 market because no one will then invest.

9 You've got to choose. If you want it to work as
10 a market mechanism, these vehicles that you implement have
11 got to be consistent with that down the line.

12 Well, I'm going to sit back. I'm not going to
13 tell anybody to invest, I'm going to say "because you can't
14 count on anything." It will be a regulatory call by the
15 person who isn't hedged and he'll exert pressure to get
16 somebody to enter into a long term bilateral that would be
17 socialized across the market and cut down the prices where
18 you['re trying to make a profit on your investment.

19 DR. HOGAN: I'd like to endorse what Roy said and
20 say that David's question, which comes up a lot, also
21 contains the seeds of an answer, at least a partial answer,
22 to the question.

23 What you were identifying in there was a market
24 failure. And it had to do with "lumpiness." If the
25 generator was so big or the transmission investment was so

1 big that before the fact there was expected there to be a
2 lot of congestion and, after the fact, there wasn't any --
3 and so it wouldn't support it -- if that is the situation,
4 the only way to do it where other alternatives are much more
5 expensive, then I think you're in a market failure problem
6 and you need some kind of regulatory solution to that, like
7 socialization of the costs of that and putting it in the
8 participant kind of funding framework mandatory.

9 But if it's not that, or there are other things
10 which might be a little bit more expensive, ex ante -- who
11 knows, given these engineering cost estimates and so on -- I
12 would stand back and say "no, there is no market failure"
13 because, if you can make small investments along the way
14 then you don't have this big impact that you're talking
15 about and you can make money on the small investments and
16 recoup them over some reasonable period of time and you can
17 let the private market do it.

18 In order to avoid the kind of problem Roy's
19 talking about where you pre-empt the market and you insert
20 yourself into having to solve every problem, which is right
21 where you're heading if you don't do that -- then this is
22 the demarcation -- what is the rule for deciding when there
23 is something that requires that regulatory solution?

24 I think that's basically "lumpiness" in the sense
25 of big scale -- it's the only way to do it. There's only

1 one site in San Francisco and that's it and you have no
2 choice -- or something like that.

3 Those are pretty rare circumstances I would argue
4 and I would look at them very hard. Then, after you look at
5 them very hard and you've convinced yourself that was the
6 only thing you could do, then you get into the regulated
7 world where you're trying to do that.

8 But I would lean against that and say that, "if
9 it's not the case, let the market solve that problem"
10 because you don't have the situation that, ex ante, the cost
11 of congestion is going to disappear.

12 It might disappear ex post -- tough, okay?

13 Because, as Roy Thilly says -- translating it and
14 saying it slightly differently, 'you have no right to
15 preserve the rents.'

16 Competition comes in and something else happens
17 and you get surprised and you make an investment that
18 didn't work out? It didn't work out. So you lose money
19 and that's the discipline that's supposed to be there.

20 But ex ante, when you're doing this analysis, if
21 you can't see that that's going to happen for sure, then let
22 the market solve the problem.

23 Say you compare transmission and generation in
24 discussing "lumpiness" -- but is there a difference?
25 Because I think to find congestion in a particular interface

1 and then rely on market signals is one thing.

2 But when you go over to the generation side and
3 you talk about scarcity pricing to rely on OP-4s, any time I
4 can have a signal above what Joe calls the "competitive
5 level short term marginal cost" in a time of shortage -- is
6 that realistic? Does that have implications or concerns for
7 or with reliability today, and so on.

8 PROF. HOGAN: I was trying to address the
9 particulars of David's question. The problem of 'we
10 desperately need this plant to run but you can't make money
11 running it' -- that's sort of the framework for a lot of
12 this conversation -- is a signal to me that there's
13 something wrong with the market design.

14 That's what David Patton has gone through as
15 examples of, and others, to sort of fix it. He has the five
16 steps, the best way to do it, then the next best way to do
17 it and so on -- until you can get those price signals right.

18 Now, there may be situations where you can't fix
19 it. You don't know how to fix it.

20 An example in the present framework would be
21 where you're providing not capacity, so it's not an
22 operating reserve problem and not energy and so on -- it's
23 basically reactive power and we don't price reactive power.

24 So my answer is, 'price reactive power.' But
25 that's another leap we have to go through and, until you can

1 do that, the other solutions don't work and you have to do
2 something else.

3 But I think these are pretty rare actually. I
4 think if you focus on the market design questions and you
5 get these scarcity pricing and opportunity cost pricing
6 correct theoretically and in practice, most of these
7 problems go away. That's my belief.

8 MR. PERLMAN: How do we measure that, though? I
9 think there's a lot of appeal to what you're saying -- as
10 soon as you raise the prices you fix the market design -- as
11 David Patton has suggested.

12 And then you guys say there's not enough
13 certainty of revenue because it's volatile -- or something
14 like that -- and you don't get the expected investment to
15 address what you've put in place.

16 Do you just say "we've done our job because we've
17 given the appropriate price signals even though the
18 financial people won't react to it as we would expect
19 rational economic people to do?"

20 Is that the extent of our job? Do we have to
21 associate what we're doing with the expected outcome?

22 Or should we do the best we can in an market
23 context then let the market sort it out?

24 PROF. HOGAN: My answer to that question, if
25 you're directing this to me, is I would look very hard at

1 these market failure problems, try to get the market
2 designed as well as we can do in that and then, unless I can
3 come up with some explanation about what the failure is,
4 like the "lumpiness" explanation, to lean toward the market.

5 If it turns out that I've put all these things in
6 place and the prices are going up, then Wall Street says
7 "we're not going to invest unless you pay us this very high
8 cost of capital."

9 I think there's a message there which is that
10 it's risky to invest in this location going forward.

11 Maybe that's a good idea -- not to invest.
12 Having you do it doesn't remove the risk. It just
13 redistributes it.

14 Unless you can show me some reason why we're
15 creating risks that wouldn't exist otherwise and that would
16 be the "market failure" kind of problem -- but if the
17 problem is we don't know what the congestion is going to be
18 int his region for the future because lots of things could
19 happen, well, that's life.

20 So maybe the right thing to do is to do a lot of
21 short term fixes, recognize that prices will go up and
22 people address demand.

23 Roy's not happy with this but shut down those
24 aluminum plants in the Northwest and go someplace else.

25 (Laughter.)

1 PROF. HOGAN: I understand that. I'll be happy
2 to do it without giving the same answer but it's not obvious
3 that that's not a message -- that you shouldn't invest
4 rather than, Oh -- if you know what investments we should
5 make and you are sure, do it.

6 But don't bother with electricity restructuring.

7

8

1 MR. PATTON: A couple of thoughts I'd add to
2 that.

3 I agree 100 percent with the notion that these
4 investments are not nearly as lumpy as people think they are
5 when they think through them.

6 In most cases what happens when you see
7 generation being built is not that the scarcity is huge and
8 then it goes away.

9 What happens is you go from 25 hours of scarcity
10 to 15 hours of scarcity -- it's equilibrium that the market
11 is searching for there and you can't overbuild.

12 And I think one thing to recognize in terms of
13 the scarcity pricing signal is I don't believe the financial
14 community is looking for stability in the spot price.
15 They're looking for stability in revenues that a generator
16 can make.

17 A highly volatile spot price will lead to an
18 attractive forward contract market for the generators so the
19 threat of price spikes and shortage on the spot market,
20 assuming they're efficient, will then lead to new generators
21 being able to sign contracts with either loads or others and
22 bring those contracts to Wall Street.

23 They're not going to show up with a forecast of
24 what they're going to make selling their power in an hourly
25 spot market and hope they get financed, I don't believe.

1 MR. BOWRING: I beg to differ by what's been said
2 by the last couple of speakers. It's fine to talk about
3 scarcity pricing and it sounds like it makes sense from an
4 economics perspective, but tell me exactly what that means
5 in a load pocket where you have all the generation owned by
6 one generator, where you have more than enough generation --
7 you have twice as much generation as you need in order to
8 serve load in the transmission -- what does that mean
9 exactly?

10 It means pricing at marginal costs. There is no
11 scarcity in that situation. If you get to the point where
12 you're scarce it's also fine to say we should let people
13 decide not to invest. We can have shortages and everything
14 will work out in the market.

15 I don't think that makes a whole lot of sense in
16 a system where ultimately you need to have a reliable supply
17 of electricity.

18 Finally, what I would add is, that you certainly
19 need to have a market mechanism to evaluate those risks but
20 simply kind of falling back on the term "scarcity pricing,"
21 I think needs to be examined very carefully before one
22 simply says that scarcity pricing is the solution.

23 MR. PATTON: You "beg to differ" but I didn't
24 hear any difference.

25 (Laughter.)

1 MR. PATTON: I don't think anyone is suggesting
2 shortage pricing where there's no shortage -- in your
3 example, you're right. If there's a surplus, the fact that
4 you've put in provisions that would reflect the value of
5 foregone reserves when you can't hold your reserves, those
6 provisions would just never set prices in a pocket where you
7 have a surplus.

8 MR. BOWRING: But ultimately your scarcity
9 pricing is administratively set -- how are you going to let
10 the market determine what that price is? Even in the
11 aggregate market you don't want to let the bids determine
12 the price. I would assume the same is also true in the
13 pocket.

14 Again, you have to have a defined reserve under
15 your first option and then somehow a market overseer would
16 set the price.

17 MR. PATTON: I don't agree but accusing it of
18 being "administrative," and that somehow is a bad thing?
19 Because all these markets have operating reserve
20 requirements.

21 The only thing that constrains how much PJM or
22 anybody else will pay to maintain their reserves is the
23 thousand dollar offer cap.

24 If there were \$2,000 of electricity available
25 from Canada to New York we wouldn't buy it because New York

1 has said "there's a \$1,000 offer cap." So implicitly your
2 reserves can't be worth \$2,000.

3 Carrying that through in terms of what is the
4 demand for operating reserves doesn't have an economic value
5 -- let's stop pretending that it doesn't.

6 You can say it's administrative but it is
7 logically consistent with everything else that we do in
8 these markets.

9 MR. BOWRING: It's fine to recognize it as a
10 value. The question is, is there a market mechanism that
11 can elicit that value as opposed to somebody setting the
12 price?

13 MR. O'NEILL: Isn't there a self-correcting
14 mechanism for scarcity pricing that, if you get it too high,
15 the buyers can bid into the market and counter the scarcity
16 pricing?

17 MR. BOWRING: Yes.

18 MR. O'NEILL: So there is a self correcting
19 mechanism?

20 MR. BOWRING: I'm sorry you have to say that
21 again.

22 MR. O'NEILL: If you get the scarcity pricing too
23 high the buyers in the market will recognize that and bid
24 into the market and that will be a self correcting
25 competitive answer.

1 MR. BOWRING: Did you find that satisfactory in
2 California?

3 MR. O'NEILL: Yes.

4 MR. THILLY: Can I just back up a little bit?
5 The facts are so important. A lot of the argument that I'm
6 hearing about generators getting entry, the price scarcity
7 and price signal inspiring that -- where I live the driver
8 for the construction of generation is the retail ratemaking
9 and the state policies that provide for the recovery of
10 fixed costs over the long term for rate base.

11 We don't have any RTPs that are going to come in
12 the market other than under a long term contract with one of
13 the existing investor-owned utilities so it doesn't change
14 market share at all or create competitors.

15 So I think those differences make -- they mean a
16 lot. You have to recognize that when you've got these sort
17 of global solutions.

18 MR. SCHNITZER: I want to make a point in between
19 the dialogue that just occurred. I've agreed with David, I
20 think at the FEMA panel, that this pricing of operating
21 reserves on a locational basis makes a lot of sense.

22 That isn't going to eliminate the need for
23 potential mitigation in those markets because you can still
24 have highly concentrated ownership of the people who can
25 provide those reserves. That's the exchange that was just

1 happening here, the fact that prices aren't clearly high
2 enough to keep people from retiring capacity when you need
3 it is a symptom of the problem.

4 We can have a pricing mechanism to help correct
5 that but that doesn't mean there isn't going to be a need
6 for mitigation there as well if we have concentration and, I
7 think, for a lot of existing -- of the circumstances that I
8 spoke of and that Joe spoke about where you don't have
9 scarcity, you have enough generation and transmission to be
10 over the problem but you've got some potential exit issues.
11 You're going to find a high correlation where you've got
12 enough concentration in that load pocket that you're still
13 going to have to have some sort of mitigation of capping or
14 over capping or whatever, even with these enhanced reserve
15 markets, which I think we agree would be better than what we
16 have.

17 That isn't quite to say, "you know, let's just go
18 to \$1,000," necessarily as the right answer in that world,
19 that's number one.

20 And going all the way back I think to that Roy's
21 original question -- I remember Bill hosted a session over
22 10 years ago where former Commissioner Stalon basically
23 observed -- "would it be so expensive to just make the
24 transmission system unconstrained?" Remember that?

25 This would all be a lot easier if, in fact, it

1 was always quick, cheap and easy to remedy transmission
2 constraints. The fact is, it's none of the above and so, in
3 everything we do, there is and needs to be an economic
4 component. We shouldn't have, as a command and control
5 goal, to eliminate congestion, to eliminate transmission
6 constraints to eliminate load pockets uninformed by the
7 economics.

8 Whatever we do has got to recognize those
9 economics and, as the speakers alluded to on either side of
10 me, "if not, what are we thinking about in terms of
11 competition and generation anyway, because we will have
12 killed that."

13 MR. BANDERA: A follow up on the distinction
14 without a difference between Joe Patton and Joe Bowring
15 before -- they both agreed that, when there's a surplus
16 situation and it was concentration that allowed someone to
17 have market power, they both agreed that mitigation is
18 appropriate under those time periods.

19 It sounded to me that before, competitive prices
20 should prevail under that time period, that competitive
21 prices is the marginal cost of the least efficient unit.

22 I was wondering if everyone agreed with that type
23 of approach from mitigation under those circumstances?

24 MR. PATTON: There's two things there.

25 In general I would agree with Joe. Whether it's

1 cost plus-10, whether it's some conduct and impact that's
2 defined by a tolerance band, when you have a surplus and
3 concentration of ownership, you're not just looking for this
4 pricing. You're also looking for withholding. That goes
5 part and parcel with it.

6 But the other side of why it is desirable to go
7 for the scarcity pricing is because now, when that does
8 trigger, when we do see those opportunity costs, the
9 mitigation almost becomes trivial because that offer price
10 isn't going to be setting a price any more. They're going
11 to be looking against where you are in the reserve violation
12 and however we've come up with it, the \$1,000, whether it's
13 the opportunity cost of the shadow prices of some
14 constraints we're seeing that are binding external markets
15 or whatever -- I'm bidding whenever I could and it's
16 irrelevant at this point because the mechanism for
17 mitigation is now saying "the right price is blank" and
18 that's what it's going to be. It makes things a lot easier.

19 These two arguments sort of disappear once we get
20 the other pricing mechanisms in place.

21 MR. BANDERA: So we're talking about a regime
22 where there's bid mitigation that restricts bids at times to
23 marginal cost type proxy -- whether it be cost plus or the
24 amp type.

25 MR. SCHNITZER: My answer to that would be

1 "except in category two."

2 If you've got an answer where that reserve market
3 is only a small number of the hours of the year and that
4 unit's a contributor, it's there for when it needs to clear
5 that reserve margin and when it's there, there's enough and
6 there's some surplus.

7 And when it's not there, it isn't. I don't think
8 marginal cost plus ten percent is going to do the trick
9 necessarily where the whole market is oversupplied and
10 there's no ICAP revenues to speak of.

11 MR. SHANKER: Then there should be some sort of a
12 locational agreement or the opportunity costs for the
13 locational reserve violation of those two hours is huge.
14 It's one or the other.

15 MR. SCHNITZER: But again, you can change the
16 labels but you're still going to back yourself into the fact
17 that, whichever market it is, it's concentrated. So if it's
18 locational ICAP market, you don't want that person to be
19 able to bid new entry prices if you don't need new entry.

20 You can have that in the ICAP market. You can
21 have it in the locational reserve market. You can have it
22 in an energy market, but it's the same problem. You've got
23 enough right now.

24 But you have concentration in terms of who can
25 offer it in terms of which every set of markets you recover

1 it from don't disturb the underlying fact that there's
2 excess or surplus and there's concentration and you have to
3 deal with that.

4 MR. SHANKER: That starts to sound like a failure
5 and if it starts to sound like a failure it may be that that
6 unit should not have been divested, or if divested there
7 should be some sort of compensatory structure for the whole.

8 Looking at both fixed and variable costs, we can
9 always talk our way into "there isn't a good mitigation
10 strategy or pricing strategy if we predicate a market
11 failure."

12 David just drew a little circle earlier. If we
13 get to a small enough situation, something that is
14 physically unique, a single generator in a specific location
15 where there are probably significant barriers to entry
16 because of the fact that they are always needed, then you
17 are probably going to look at a solution that is not
18 predicated on markets, at least not as fully dependent on
19 market price and has a significant administrative element to
20 it which says "let's try and send the best price signal we
21 can, take a look at what's missing and pay the rest."

22 MR. SCHNITZER: I don't think even in the
23 circumstances I was referencing that you can't rely on offer
24 caps of some sort. Just saying that they're going to be
25 \$1,000 or new entry by default may not be the right answer

1 in those circumstances. There may be a bunch of those and
2 they may be persistent.

3 But I think that's an indictment of the whole
4 market based system. I agree with what's been said here,
5 that we ought to stick with offer caps as opposed to price
6 caps or other contractual arrangements where we can.

7 MR. THILLY: Can I take a moment to just respond
8 to Michael's question about transmission? I'm not
9 suggesting that you don't take economics into account in
10 building transmission. I'm not worried about overbuilding
11 and I don't operate under the illusion that we really are
12 going to get a robust system that eliminates all load
13 pockets.

14 But we can get a lot closer than we are today.

15 What's key is, we've got to recognize that there
16 are many more and more difficult barriers to the
17 construction than building a peaker or a combined cycle
18 generation unit.

19 The planning process is complex. It has to
20 involve a number of different parties. It's got to balance
21 needs. It takes a lot of time. It's transmission
22 facilities have to meet multiple purposes. It's not a
23 simple world.

24 We increased import capability in Wisconsin about
25 3 or 4 hundred megawatts in the last year and a half. The

1 result has been creation of many internal constraints
2 between the control areas within Wisconsin.

3 Hard -- state siting issues are much more complex
4 on transmission than generation. Then we have a number of
5 players who would be hurt by the construction of
6 transmission and who have a lot of power.

7 So we've got to take a different approach than
8 just simply saying "compete against the construction of a
9 peaking unit." That's not going to solve or problem.

10 MR. TIGER: Perhaps to get back to some of the
11 financial point of view, we've had a lot of discussion about
12 the energy price to go back in the financing markets today
13 or going forward in the absence of a contract, regardless of
14 the level of whether electricity, the energy price, is
15 mitigated -- will you get new entry into load pockets solely
16 based on volatile energy prices -- as a first question?

17 MR. NAPOLITANO: This will be a generalization
18 but the capital that is sophisticated enough to understand
19 the conversation that just occurred, to quantify what was
20 just said, to price-risk of what was just said and decide to
21 bear what was just said -- that capital is currently funding
22 other ways to make money than electric generation --

23 (Laughter.)

24 MR. TIGER: That said, right? What may be of
25 David's five elements and here we're predicating that you

1 actually need new generation in a load pocket, what would be
2 most amenable to capital actually committing to that load
3 pocket --

4 MR. NAPOLITANO: Several of the gentlemen
5 throughout the course of the conversation really have
6 brought out some of the concepts we have started with,
7 separating fixed and variable risk and return on and return
8 of capital -- one of the comments I made in my remarks was,
9 debt learned a lesson the last time when they took equity
10 risks -- it doesn't want to do that again this time.

11 We all understand that debt is the cheapest cost
12 of capital in the capital structure to aim at these
13 solutions and a lot of the conversation that has occurred
14 has really talked about the revenue in the market as opposed
15 to what an investor will look at as a forced cost to decide
16 whether they want to bring the capital or not.

17 Debt goes first then equity is going to have to
18 do some sensitivities to decide where its tolerance is.

19 So there's a minimal cost that equity does have
20 to get comfortable with and the tension is between that
21 implied cost and where all of these mechanics on deciding
22 revenue line up to see if there's a positive intersection
23 point.

24 But I'd argue without the debt the equity becomes
25 a lot more interesting because of your saying it's only

1 equity that can invest in this market -- you've got a cost
2 of capital that just doesn't work for something like
3 infrastructure.

4 MR. BALIFF: I think the thing we're not also
5 taking into account is again the cost of building in these
6 load pockets. We can talk about whether the market signals
7 are there but you can't leave out the nature of the
8 construction, right? The nature of the construction right
9 now, at least in my experience in the three or four projects
10 we're trying to build in New York, Wisconsin is almost
11 unknown when you look at projects that very sophisticated
12 people who understand construction are seeing two times the
13 cost in the eventual price -- you're talking about not being
14 able to get the equity sponsorship first and, as Frank
15 talked about, in order to analyze this for debt, there's
16 just so many more opportunities to make money -- when the
17 investors, whether it be taking place on regulatory risk in
18 California and buying the debt, the distressed debt of some
19 of the utilities there, there's just better and easier ways
20 and more certain ways to make more money.

21 That's really I think the bigger issue.

22 That being said, there is merchant risk being
23 taken today. The SES transaction I keep going back to is
24 about to get financed in the next two weeks. There is a
25 merchant risk there. That contract is only 10 years and

1 that contract, if people get the next present value, is a
2 pretty long contract in today's world. That still cannot
3 finance the asset, the cost of the asset is just too high.
4 It's around \$2,000 a kilowatt. That's a coal plant in
5 Arizona, okay?

6 So when you finance these plants in load pockets
7 there's going to be a certain amount of merchant risk --
8 what you call an amount of volatility risk -- that is
9 primarily being taken by the equity and it monetizes itself
10 by how much equity is available in the capital structure.

11 There is a way possibly from a regulatory
12 standpoint -- I think New York thought that the Liberty
13 Bonds, for example, would help finance these types of
14 infrastructure. I can tell you that will not happen.

15 Liberty Bonds have a prerequisite of being
16 investment grade -- right now to get an investment grade
17 rating from the agencies and, by the way, we haven't even
18 mentioned the rating agencies, okay?

19 And you know Frank and I are trying to follow
20 along, both Frank and I have I think Master's degrees in
21 engineering -- we're trying to follow these agencies.

22 Forget about the agencies -- they're taking a
23 very different view. You're really looking at very
24 sophisticated, what we almost call the "leveraged market" --
25 high yield investors looking at these merchants and Frank

1 introduced it with a very good comment, "There are better
2 ways to make money elsewhere."

3 MR. SHANKER: The conclusion on this though
4 should be that everything you do to reduce the risk of that
5 hides the price of that to the people who are consuming at
6 the margin, in the load pocket. That's what's disturbing,
7 the fact that someone is coming in and saying "yes, I really
8 need that five-year contract or that eight year or 10 year
9 contract" -- to make it work.

10 The question is, 'why isn't the load in those
11 locations willing to step up to that obligation if that's
12 what's necessary?'

13 And if they aren't what are we doing to diffuse
14 the information such that you're sitting here and we're
15 undercutting the market potentially by taking an action on
16 an RMR agreement that somehow socializes those costs -- so
17 that we can keep people from seeing the fact that it might
18 be a \$2,000 a kW in-city unit.

19 That is ridiculously expensive, not because you
20 can't enter the market but because it's ridiculously
21 expensive in certain locations to build. There's nothing
22 wrong with that. I'm not troubled by the fact. I mean,
23 there's a lot of things that are expensive in New York.
24 Almost everybody that lives in this area knows, to replicate
25 your housing in New York, you pay five or six times more.

1 It's not inconsistent with that to say "yes, it
2 costs two or three times more to provide electric power
3 where it is needed for reliability inside the city."

4 The question is, 'do you want to set up policies
5 that hide that fact from anybody's consumption?'

6 MR. PERLMAN: A question that I have for you -- I
7 understand what everybody is saying here, what Mr. Thilly
8 said about "associating the retail regulation with the
9 wholesale regulation" in making all this work seems to be an
10 issue to me.

11 In a lot of the markets we're talking about, the
12 distribution utility is a default service provider with
13 maybe a one-year RFP or something like that and they have,
14 as far as I can tell, no incentive to enter into any kind of
15 long term contract -- in fact, they have a disincentive in
16 the retail marketplace from a regulatory perspective because
17 they're trying to incent retail competition and the retail
18 service providers don't have the balance sheet to do this
19 nor do they have the customer base going forward.

20 So we're stuck with the situation where the price
21 signals you're talking about may incent a rational LSE to do
22 this if they weren't stymied by other types of regulatory
23 incentives and were stuck in this betwixt and between world.

24 These guys are saying -- what they're saying and
25 the people whom we would expect, all other things being

1 equal, to sign the contracts won't do it because of their
2 other incentives.

3 I don't know where we go from there but that's I
4 think pretty much what we are seeing today in a lot of
5 places and it doesn't mean that any of it is wrong. It just
6 needs to fit together and I'm not sure it does.

7 Do I have that wrong?

8 MR. BOWRING: I think the institutional issue you
9 identify, particularly as we move away from integrated
10 utilities where the transmission owner and the LSE are the
11 same company -- you've identified exactly a really
12 significant institutional issue and an incentive issue going
13 forward -- that is, LSEs will not be and are not now long
14 term entities.

15 Therefore they are not going to be there a long
16 time. There's no guarantee they're going to be around a
17 long time. Not only do they not have any desire to enter
18 into long term contracts, but they might not even be able to
19 financially. That's certainly an issue.

20 And then it links back to the financial question
21 because, while what Roy said is certainly a fair conclusion
22 to draw, that the risk needs to be priced into the value of
23 the power in the load pocket, it's also the case that you
24 need a transparent, really straightforward mechanism, which
25 is what the investment folks are telling us, that shows

1 people they can make enough money to cover the costs and
2 will there fore actually invest.

3 We don't want to be creating, adding, regulatory
4 risk -- neither do we want to be suppressing it.

5 MR. THILLY: There's another element to what
6 you're talking about that makes it even more difficult. In
7 my area, if you have a utility that has part of its service
8 in a load pocket, say the Upper Peninsula of Michigan, which
9 is even worse than where I am, and a lot of territory not
10 there -- they, on a retail basis are going to average their
11 nodal costs and the folks where the real problem is are not
12 going to get the signal.

13 The only entity that's going to get the signal is
14 the small municipal entity that's already there. That
15 creates a tremendous equity issue, I think. The signal
16 doesn't go through. The people consuming don't get the high
17 price signal we're talking about but the generator gets the
18 high price.

19 MR. HOGAN: I think this is a great opportunity
20 for exercising regional deference --

21 (Laughter.)

22 MR. HOGAN: -- so the need to match wholesale and
23 retail is certainly a legitimate issue and you want to make
24 sure you're not doing something which precludes people from
25 doing whatever they want to do on the retail side.

1 But I don't think that that translates into "it
2 is the job of the federal regulator to undue what the state
3 regulators are doing with their retail regulation."

4 If they choose to have a big zone in the state --
5 I wouldn't recommend that they do it, but I would also even
6 more strongly recommend that you not try to undo what they
7 just did -- because they chose to do that there.

8 If they choose to have not a core-noncore market,
9 but to have all retail customers dealing with the
10 marketplace and LSEs who last for six months and they keep
11 switching back and forth, that's their choice.

12 I wouldn't do it that way personally but that's
13 their choice. I don't think you have to undo that and I
14 think if you have a viable wholesale market to design, and
15 the property rights that go with it and all the other kinds
16 of things we've been talking about here, you can leave it up
17 to them to decide.

18 Some of these customers are big enough so that
19 they can internalize these problems and they'll contract and
20 they'll deal with the problem.

21 The munis that actually have load serving
22 obligations will go contract if the property rights are
23 there -- that's an issue that you have to worry about,
24 making sure that they can get those things.

25 But I don't think you should be worrying about

1 problems like really bad retail design in the state. We
2 have to change the wholesale market design in order to undo
3 what they're doing in the state because I think that's a
4 quagmire that you're never going to get out of.

5 MR. COLEMAN: I'm not suggesting that. The only
6 point I was making is that what we're hearing is, if you
7 stimulate pricing, the LSEs may contract. But if there's
8 some intervening state regulatory program which may be fine
9 -- I don't think we should tell them to change.

10 MR. HOGAN: Then they won't contract.

11 MR. PERLMAN: That's right. Have we achieved our
12 goal or should we care?

13 MR. HOGAN: You shouldn't care.

14 MR. SHANKER: All you do is drive the risk up
15 because the guys on that side of the table are going to
16 place a price on doing this that's going to even be more
17 expensive.

18 We go through this discussion and you've probably
19 heard me a lot say that we shouldn't let the retail tail wag
20 the right price signals at the wholesale levels of the
21 wholesale dog -- we go through this all the time.

22 We do lots of really weird things in wholesale
23 market design to accommodate bad retail design and, if the
24 net result of that is that retail regulation is increasing
25 the risk of wholesale capital formation, but we're out of

1 the way of it, that's the way it comes out.

2 Otherwise you just cascade. If you want to stop
3 that then you're going to say "I'm going to tell you what
4 the right place should have been" despite the fact that
5 they've got this bad design and the only way you're going to
6 be able to do that is you're going to step in and start
7 contracting.

8 Who are you going to contract for it? You're
9 going to contract with the retail customers via the LSEs as
10 the ISO or the RTO -- we're going to be back in central
11 planning and we're going to get rid of the market.

12 If you want that solution, we should step back
13 and do a whole bunch of other things consistent with that,
14 as opposed to piecemeal pick out stuff that will suppress
15 price.

16 If you want to do it, be fair and compensatory
17 across the board and say "I give up," but to sort of cherry
18 pick and say "I'm-a going to mitigate or control costs" or
19 suppress price in one area where there is a true price
20 signal coming through, but it just isn't "acceptable" and
21 the retail programs don't work with it -- this isn't really
22 viable long-term. It's a disservice to everybody in the
23 market.

24 MR. GRAMLICH: Could I follow up and maybe get
25 some other comments on that? It strikes me, if there is

1 scarcity in a load pocket, investment is needed if the LSE
2 for whatever reason is not making the investment, Roy put
3 out the theory that the alternative is the RTO and I think
4 we're seeing that proposal in various forms crop up in a few
5 of these markets, going back to kind of the original concept
6 of an RTO and ISO.

7 Is it an appropriate role for the ISO to be in
8 that position? You've been doing this for a long time.

9 MR. HOGAN: I will argue that, no, you have to
10 talk about what the alternatives are but I think, just as
11 Roy said, it's the slippery slope problem.

12 You just inevitably are going to get into -- that
13 creates incentive which creates more problems that you have
14 to intervene and pretty soon you're doing everything.

15 Unless you can find some way to define a
16 principle at which you're going to stop -- I don't know how
17 to avoid that problem.

18 If the customers are just not going to do
19 contract and they're just going to live with high and
20 volatile prices and shortages and lights going out, I don't
21 think that's consistent with the notion that we got the
22 market design right and the scarcity prices are correct and
23 there's no generation that's prepared to go in there.

24 It might be better if customers did it on their
25 side -- it might be easier and so forth, but at some stage,

1 the generation's going to go -- and I'll invest.

2 (Laughter.)

3 MR. KLEIN: Rob, I'd also like to respond a
4 little bit on this because I think the Commission should be
5 encouraged by what is going on in New York City, which is
6 the one area that was on the top of David's list where all
7 the market design elements are ripe for a load pocket.

8 You know, there are projects that have gotten
9 built. There's East River Repowering, Ravenswood Four, SES
10 and one of the most innovative projects we've seen is a
11 merchant DC tie, Conjunction, which is bringing 1,000
12 megawatts from Upstate New York down into New York City and
13 is able to do that on a merchant basis in part because all
14 the market design elements are right.

15 It's also the case that there are probably 10,000
16 megawatts of other projects, some of which are not getting
17 financed in New York City -- maybe what we're seeing is the
18 right result when the market design is right and New York
19 City is really just about the only place where it really is
20 right for a load pocket according to David's list.

21 MR. PATTON: Let me modify and just say what I
22 said about New York City --

23 (Laughter.)

24 MR. PATTON: It was -- its the only place where
25 they're attempting to do any of the first three items on the

1 list. They're certainly not doing the first one. But they
2 do have the locational ICAP which is helpful.

3 MR. THILLY: I can't help but respond to the
4 position "we should ignore reality." The first thing I said
5 was "you've got to pay attention to the facts" and ignoring
6 the retail reality, the economic drivers and the facts in
7 those situations because somehow we think the retail system
8 is bad results in implementing this in large parts of the
9 country and in the imaginary world that exists on paper, but
10 is not going to produce the results that you want.

11 If the objective is net benefit to customers
12 you've got to design a system that's reasonably likely to
13 produce that for customers and not just simply ignore those
14 folks that are in states where you think they've got a bad
15 system.

16 I don't think that results in a just and
17 reasonable rate in those areas, the wholesale which is the
18 Commission's obligation --

19 MR. GRAMLICH: Roy, you don't disagree with the
20 idea that it should be the load serving entity's obligation
21 to make the investment, do you?

22 MR. THILLY: No.

23 MR. GRAMLICH: Your state certainly has the
24 ability to do this.

25 MR. THILLY: I agree.

1 MR. GRAMLICH: You would not support the ISO 30
2 RTO negotiating and signing long term contracts.

3 MR. THILLY: No, I don't like that model. I'd
4 much rather do it myself.

5 MR. GRAMLICH: On the institutional question, I
6 think you all agree, or most of you agree.

7 MR. HOGAN: If Roy is referring to me, saying we
8 should ignore the retail, that's not what I'm saying. I'm
9 saying there are things you should do that are under your
10 control that are extremely important to do because you want
11 to support the retail markets, like getting all these design
12 issues correct, like the allocation of the property rights
13 and the FTRs that he's legitimately worried about -- make
14 sure that's done well so that you can go forward. You've
15 got all the other problems in setting that thing up.

16 But after you've set that up and you give them
17 all the opportunities to participate in this, if they decide
18 they're going to give away electricity for free, if they're
19 going to stop, take all the meters out and they're just
20 going to let people consume because it's better because it
21 attracts industry, I don't think that you should just say
22 "well you know I guess we just have to solve that problem
23 for them somehow."

24 If that's the choice they make they should live
25 with the consequences of that.

1 So there are a lot of things you should do so you
2 don't ignore them but you don't have to undo things that you
3 don't like that they're doing and then torque the design of
4 an efficient wholesale market in order to correct for the
5 things that you don't like that they're doing.

6 MR. PERLMAN: Can I ask a locational ICAP
7 question? Does locational ICAP raise questions of
8 locational market power if you end up with a situation where
9 the entity that is in the location has some kind of
10 concentration issue -- and how do we address that problem
11 and not blunt the price signals that the locational ICAP is
12 designed to create?

13 MR. PATTON: I don't think it creates the
14 problem. The problem exists no matter what you do. In any
15 of the alternatives, if you have somebody who is the
16 dominant supplier of capacity in that area they can create
17 high energy prices, high capacity prices -- I think what you
18 want to do to mitigate that in the locational capacity
19 context, I think the demand curve for capacity is very
20 helpful, not allowing people to withhold the capacity.

21 In other words, if I need 1,000 megawatts in some
22 area, you need a system that recognizes how much you have
23 and doesn't allow a supplier to make you believe you only
24 have 800 megawatts by withholding some of this capacity.

25 So it's a problem that's much more acute in the

1 locational ICAP. It's also a problem that you confront in
2 broader capacity markets although not as severely.

3 MR. BOWRING: Could I just add, given that I
4 think that all capacity markets have almost by design market
5 power issues, it's certainly the case as David said that
6 although the local ICAP doesn't create more market power it
7 certainly reveals it as you move to a small area -- there's
8 absolutely no question you're going to have extreme market
9 power and selling capacity.

10 That's why, rather than basically setting a
11 price, a local price, which is what local ICAP ultimately is
12 going to boil down to, unless you have some, again, market
13 mechanism for example, which permits new suppliers when you
14 need new capacity to bid against one another, for example an
15 auction, in an market mechanism in order to reveal a market
16 based price, I think the auction alternative has to be
17 preferred to the alternative where you simply are setting a
18 local ICAP price.

19 Unless I'm misunderstanding David I think using a
20 demand curve or telling people what they have to bid if they
21 can't withhold is effectively equivalent to setting the
22 local ICAP price.

1 MR. BANDERA: Could someone explain the
2 difference between what the demand curve for ICAP is versus
3 sort of contrasting it, a vertically inelastic demand for
4 ICAP? It seems to me when you define an ICAP requirement
5 and say you're willing and that's the requirement, that's
6 just an inelastic demand curve versus putting in place.

7 MR. PATTON: That's right. It's variable
8 capacity. But most of the capacity markets at least when
9 they began had vertical demand curves. So we said the
10 requirement is the single point and the deficiency price is
11 some price that we're going to cap the capacity price at.
12 What the demand curve does is attempt to recognize the fact
13 that an incremental capacity over the minimum requirement
14 has a number of benefits so that for both reliability and
15 the fact that it reduces the instance of a shortage on the
16 market the effect it has is it changes the capacity
17 suppliers' incentives because if they withhold instead of
18 going from a price that's close to zero to a cap, the price
19 effect is mitigated.

20 MR. SHANKER: Derek, you have two sort of
21 fundamental problems with the capacity markets -- inelastic
22 supply and inelastic demand. The demand curve is an attempt
23 to make -- I want to say add -- elasticity on the demand
24 side and to allow variable quantities so that you might be
25 happier with 17 percent instead of 18 percent, pay a slight

1 premium for that if there's a shortage.

2 The other side which people are looking at and
3 you can do this and, to some extent, it's a variant of what
4 Joe was talking about in the auction structure, is create
5 elasticity in the supply side by creating a window that's
6 wide enough for new entry and have people compete to offer
7 on that basis and you can have both of them together.

8 You can mix and match because fundamentally what
9 you're trying to do is beat the market failing on inelastic
10 supply and demand by giving an opportunity on both sides for
11 a response.

12 MR. O'NEILL: Joe, can I ask a question? I don't
13 disagree that when you need capacity it may be appropriate
14 to conduct an auction. Why doesn't the LSE or the state
15 oversee that auction?

16 MR. BOWRING: I don't have any vested interest in
17 who runs it. I think it's important that it be run in an
18 competitive manner.

19 The point David made earlier is that LSEs by
20 design typically aren't in a position and don't have the
21 incentive to do that. Maybe the state or some other entity
22 -- it doesn't have to be the ISO but what it does have to be
23 is an institution that has the ability -- you're not buying
24 the capacity, you're not participating in the auction.
25 You're simply acquiring it on behalf of the load and the

1 load would be obligated to pay it.

2 The ISO was clearly in a position to do that but
3 there's no reason it shouldn't be the ORT rather than the
4 state.

5 MR. O'NEILL: In the white paper we sort of
6 indicated that resource adequacy was a state issue and that
7 the state was responsible for it. Why wouldn't it be the
8 responsibility of the state or the local LSEs?

9 MR. BOWRING: Again I think there's a very good
10 reason why it's not the local LSEs. We've set it over
11 another --

12 MR. O'NEILL: Because the states chose a bad
13 retail market design?

14 MR. BOWRING: -- I'll leave those words to be
15 yours.

16 (Laughter.

17 MR. BOWRING: But nonetheless the way things are
18 structured is LSEs don't have the incentive or perhaps the
19 financial capability to enter into a long term contract so,
20 given that and given that there's a need for a long term
21 contract in order to provide revenue stability to generators
22 to solve reliability issues in the load pocket in order to
23 make them financeable, clearly there has to be some way of
24 obligating load to pay the costs of the generation power for
25 expenses if it is.

1 MR. O'NEILL: Is the reason why because they
2 don't see the full cost of not hedging?

3 MR. BOWRING: Is the reason why what?

4 MR. O'NEILL: If you don't have the incentive to
5 enter into long term contracts maybe the reason is that you
6 don't see the full cost of not hedging.

7 MR. BOWRING: LSE wouldn't see the cost. LSE
8 would simply be passing it through to the load.

9 Ultimately the institutional problem is there's
10 not an entity in the market who is interested the same as
11 the load.

12 MR. BALIFF: There's an important financial
13 element to this, too.

14 MR. NAPOLITANO: When you talk about this
15 relationship between the wholesale and the retail and the
16 pocket you're really talking about who should bear this
17 cost. Everybody agrees there's an incremental cost and
18 furthermore what should that cost be?

19 One of the problems, when you have certain levels
20 of retail rate disaggregation is, in the interim which we
21 learned in California is, when it's not clear who should pay
22 what, the only person with the working capital to do it in
23 the interim period is the LSE until they burn out their
24 working capital. Then it's too late to decide what should
25 have been done before.

1 So you understand there's this tension between
2 what the Commission can and should do and what the states
3 can and should do. But there is a direct financial
4 relationship between the two and capital won't step on
5 either side of that equation until they understand how that
6 relationship really flows.

7 But if it's complicated also by the rating
8 agencies which are taking right now a very strict approach
9 to these contracts -- as much as we also cover the
10 generators we also cover the LSE -- the rating agencies
11 right now take a very strict approach to these contracts and
12 clearly make them debt equivalent.

13 Which is why you see many low capitalized
14 utilities having very much lower ratings than you would
15 think primarily because they have what you call "computed
16 debt" from the rating agencies.

17 That's another reason why you're not seeing these
18 contracts. There's a lot of uncertainty on that.

19 MR. O'NEILL: Is that new? Why hasn't that
20 happened in the past?

21 VOICES: It has.

22 MR. SCHNITZER: People now have an appreciation
23 of how out-of-market those contracts can be which they
24 didn't before. But two points on the locational ICAP that I
25 just want to come back to.

1 The first is there can be concentration issues as
2 we've said that have to be dealt with in mitigation. The
3 second is locational ICAP markets are not a full substitute
4 for RMR and if you look at what people define to be load
5 pockets and you ask yourself "is every generator within that
6 load pocket electrically fungible from an RMR perspective"
7 the answer is no.

8 Particularly with the reactive considerations you
9 will have with subsets of generators or individual
10 generators which have RMR conditions that are unrelated to
11 the other generators in the load pocket there are some
12 benefits and some improvements in the market from going to
13 that concept, but you are still going to have particularly
14 for reactive, you're going to have much more localized
15 issues which raise their own concentration issues that are
16 not addressed fully by the locational ICAP.

17 MR. PERLMAN: What do you mean by "must be
18 addressed in mitigation?" How would you mitigate?

19 MR. SCHNITZER: I think you've got a couple of
20 concepts here on the table. I haven't worried about the
21 ICAP solutions so much as some of these other energy market
22 and whatever solutions but I think you've got something
23 short. The concepts I laid out or the principles that I
24 laid out say "replacement cost is not the right mitigation"
25 where you don't have scarcity in the load pocket and you

1 have more than enough supply in the load pocket and you have
2 concentration saying you can bid up to replacement cost --
3 is probably not the right answer.

4 MR. THILLY: Can I come back for a moment to
5 Dick's question which had to do with whether the load
6 serving entity has an incentive to do longer term contracts?
7 I said I would like to do it and not have the RTO do it but
8 my economics are, my driver is delivered cost of power to my
9 customers, bottom line, which is a different set of drivers
10 and economics than some other folks have and an obligation
11 to serve state -- those utilities have got to have the
12 capacity and meet the state reserve requirements or they're
13 going to get hammered in the rate setting process so they do
14 have an incentive to enter into those contracts which may
15 not be true in other parts of the area.

16 So a 'one size fits all' doesn't work very well.

17 The biggest problem we have on those contracts
18 'easy to build a peaker -- very difficult for a small entity
19 to get long-term baseload capacity.' That is a market where
20 there is a lot of market power concerns and it is made even
21 worse by the fact that the market designs don't provide long
22 term FTRs for new resources.

23 I'm going to probably invest in a coal plant but
24 it's going to be very, very costly.

25 The whole justification is the delivered cost in

1 energy -- that's the only basis that's economic and if I
2 don't have a long term FTR to go with it, I don't have it.

3 I don't know whether these guys will finance it
4 because the economics is based on something -- it's
5 speculative on that long term FTR. That is a huge problem
6 going forward.

7 MR. MEAD: I'd like to ask a question about "must
8 offer" requirements. We've heard several speakers address
9 the issue of how to address economic withholding and bid
10 caps of various sorts were suggested.

11 Is there a role for some sort of policy to
12 address physical withholding? Is there a rule for requiring
13 basically a "must offer" requirement? If so, what would the
14 nature of that "must offer" requirement be?

15 MR. BOWRING: Let me just say very quickly in PJM
16 one piece of selling capacity is selling a "must offer"
17 obligation -- when you sell capacity to the market one of
18 the things you're selling in addition to effectively a call
19 at the market on your energy during emergencies is the
20 obligation to offer that exists. It doesn't make monitoring
21 physical withholding any easier and as anyone who's tried to
22 do that can tell you, it's well nigh impossible -- it's at
23 least very difficult.

24 Nonetheless there are basic metrics that one can
25 track, including outage rates and availability rates and

1 other things, that let you know whether you have a problem.

2 MR. PATTON: Clearly you have to address physical
3 withholding, because if you mitigate economic withholding
4 they can just accomplish the same outcome by physical
5 withholding. So you have to address it.

6 I think thought that when you look at "must
7 offer" if you define physical withholding on market power in
8 general as the ability to raise prices above competitive
9 level profitably, in this case by withholding the sources,
10 that's really what you should be addressing.

11 What I find looking at these markets is that the
12 vast majority of generators in the vast majority of
13 conditions don't have the ability to raise prices. If you
14 were to ask me, "is a generic 'must offer' provision
15 necessary?" I would say no. What is necessary is a
16 prohibition against physically withholding to exercise
17 market power.

18 That may translate into effectively a "must
19 offer" provision in two percent of the hours for a certain
20 generator and not 100 percent of the hours. In those cases
21 they can derate their unit and take it off line. They can
22 shut it down for a season and it won't have any measurable
23 effect on the market prices.

24 If that's true it's okay and it's not physical
25 withholding.

1 MR. SHANKER: You've got to be very careful.
2 Even though it sounded like New York and PJM were the same
3 in some sense on this, they're not at the detail level.

4 As Joe said, the ICAP obligation is both an
5 obligation to bid into the day ahead markets and an
6 emergency call.

7 In New York the obligation is to offer into the
8 day ahead market but actually the emergency call may not
9 transpire into real time because of fuel considerations.
10 We've seen recently people are releasing fuel into the real
11 time having met their obligations to offer into the day
12 ahead markets and it gets even more complicated in that you
13 sometimes have, although I misread a contract the other day,
14 I thought someone had a very good motivation to withhold in
15 the day ahead market because the product was hedged and
16 offered in real time.

17 A reasonable evaluation would say that wasn't
18 physical withholding and it wasn't anti-competitive.

19 So the bottom line is, you need to do what David
20 said which is you've got to see if somebody is withholding
21 in the context to exercise market power and the mandatory
22 offer may be a good summary statistic but it's not really
23 what you want to be focusing on. You want to focus on the
24 mechanism that may be getting an unreasonable profit in
25 that.

1 MR. MEAD: The ICAP obligation that Joe and Roy
2 talked about is in a certain sense something that a
3 generator voluntarily agreed to take on -- what about for
4 generators that don't take on that obligation voluntarily or
5 in markets that don't have ICAP obligations, do we need to
6 worry about "must offer" in that context?

7 PA: They did voluntarily take something on.
8 They came and asked you for market based pricing. The fact
9 that they're not being paid for capacity for reliability
10 purposes doesn't give them a free pass to exercise market
11 power -- the quid pro quo they got market based pricing.

12 That is a confusion then that has percolated
13 through New York for a very long time because there's a
14 requirement to bid in the day ahead market for capacity
15 sellers.

16 Capacity resources -- in fact I think Roy asked
17 me early on why should non capacity resources be subject to
18 market power mitigation? The answer is, because it clearly
19 has nothing to do with whether you sold capacity or not.

20 MR. SHANKER: I think that's where the
21 distinction comes. In these markets there's a contractual
22 obligation through the ICAP mechanism -- where someone isn't
23 involved in that market mechanism there is no obligation to
24 offer but there isn't a free pass to exercise of market
25 power. That's a significant distinction. Nobody's going to

1 go around saying it's okay to exercise market power.

2 The issue is though it's also okay to
3 discretionally operate in facilities as long as you are not
4 exercising market power.

5 MR. THILLY: It's so difficult to distinguish
6 between scarcity and withholding. It may be that it's
7 possible but it's very difficult. I think that's true.
8 Having a resource adequacy requirement that covers fixed
9 costs allows you to have a "must offer" requirement because
10 the capacity cost has been covered. That makes it a much
11 simpler way to deal and a much safer way for the customer.

12 You also have to recognize by the fixed costs
13 covered through retail regulation in many cases they are or
14 through long term bilateral wholesale contracts -- if that's
15 the case there's no reason why in a competitive market that
16 energy would be bid at marginal plus some profit -- that's
17 what would happen because they would be making money.

18 We've got to take account again of the facts and
19 try to set it up as simply as possible with as little gaming
20 opportunity as possible.

21 MR. PERLMAN: Can I ask a question about that
22 real quick? It follows up on something Roy said earlier.

23 The scarcity pricing you all are talking about is
24 I assume the type that has really real clear cut sort of
25 break points when you reach a period of scarcity when the

1 operating reserves have been affected.

2 In all other circumstances, am I correct that you
3 would have no scarcity pricing that would happen? Sort of
4 volitionally by the market participants?

5 It would all be subject to the same sort of
6 mitigation that you have all the other times, so it's really
7 an administrative break point and I understand those things
8 are necessary and shouldn't be sort of denigrated as David
9 Patton said earlier -- but they're a judgmental set of
10 rules.

11 I just want to make sure we're all talking in the
12 same place where you start scarcity and where the price
13 goes. Is it an administratively established process that
14 has some basis in maybe the operating reserves in the market
15 or some base in some structure but is not going to happen
16 sort of on its own? Did i get that right?

17 MR. SHANKER: Yes. That's a reasonable summary.

18 MR. KLEIN: Let me just add to that that it's
19 important that what's defined as "scarcity" includes all the
20 different things that the ISOs do potentially or LSE do when
21 things get tight. There ought to be some mechanisms if they
22 have an operating procedure that says "okay I'm going to
23 violate certain transmission constraints." If that results
24 in prices collapsing then we don't have good scarcity
25 pricing.

1 If demand side resources get picked up, 1,000
2 megawatts get picked up and they go in as zero offer units,
3 then the price is only \$50 because we don't have an
4 operating reserve problem.

5 That's not good scarcity pricing. So it's a much
6 more complicated thing. We'll see how New York does this
7 summer but I suspect there's going to be tricky little
8 details in not out of an intention to harm the market and
9 scarcity pricing but that it will be very hard to capture
10 all the different things that the operators do in real time
11 to make sure load is served. That really should look like
12 scarcity.

13 MR. PERLMAN: The reason I'm asking from a
14 regulatory perspective and I'm an economist not a lawyer so
15 it says here from what I can tell half the economists will
16 say it's scarcity pricing. The other half will say it's the
17 exercise of market power and it's the same thing.

18 I know there's debate about that.

19 MR. O'NEILL: Speak for yourself, Dave.

20 (Laughter.)

21 MR. PERLMAN: Dick is very clear and in helping
22 us do what we're doing in order to have a better approach to
23 mitigation and scarcity pricing and have it embedded in the
24 regulatory regime it would seem to me for us to do this we
25 need to be very clear and to say "in this set of activities

1 you're going to be subject to mitigation or to these
2 circumstances." End of story.

3 And when these circumstances occur, as Roy said
4 before, "scarcity pricing will kick in" and it doesn't
5 really matter what you do because the price is going to be
6 what the price is going to be and then we would have a whole
7 lot less ambiguity into how to implement rules and maybe a
8 little more clarity on how to do mitigation and address
9 local market power because we've sort of taken that out of
10 the hands of the market participants and put it in the hands
11 of the structure.

12 MR. PERLMAN: I agree with you. What most
13 economists would agree on is, if you can't point to anyone
14 withholding any resources -- in other words, you're fully
15 utilizing your resources and you still can't meet your
16 operating reserve requirements or whatever, clearly you're
17 in shortage.

18 I think designing the mitigation, that's the
19 premise in the conduct and impact tests that are used to
20 trigger mitigation in New York, the conduct tests are
21 intended to detect when there is withholding.

22 If you're not detecting any withholding and
23 you're short of operating reserves, you can have confidence
24 in the scarcity pricing signal. It's the reason why it's
25 important to have relatively transparent thresholds and

1 understandable rules about when you exceed those thresholds.

2 MR. SHANKER: It's worth clarifying the point
3 that Abram brought up -- there's two different things going
4 on. When we say it's sort of automatic that's correct but
5 there are situations where the operating rules change and so
6 what you price to may be inconsistent with the reality of
7 the operation.

8 The best example is in New York. There was a
9 fire at a substation and several cables were lost. The
10 operators legitimately said "time to be super conservative"
11 and they turned on everything at minimum.

12 Basically they're operating to a third or fourth
13 order contingency. Had you priced in the LMP algorithm to
14 that, prices would have gone up if you'd shown the
15 contingencies, the third and fourth order contingencies --
16 what happened was people had all those units running at
17 minimum and then priced against the first contingency.

18 Under normal dispatch rules the prices went down.

19 I think we reached agreement that's never going
20 to happen again. You can ask David.

21 (Laughter.)

22 MR. SHANKER: The point is that there are a lot
23 of details in this and we've had similar things in PJM --
24 PJM operators have gotten very conservatives at times of
25 peak and did not cycle some of the combustion turbines.

1 They kept them on. They were afraid they wouldn't restart
2 so we had some excess generation that was suppressing price.

3 It was an absolutely legitimate operating
4 decision. There was no reason to question it but we have to
5 think about what things like that do to pricing because
6 you're suddenly saying the system as a whole is a little
7 more edgy. Maybe I should have a more conservative
8 operating profile and that has to set a different background
9 for how we price in the market mechanism.

10 MR. O'NEILL: What you're saying, Roy, is that
11 the operators decided to bring on more reserves but it
12 wasn't priced properly?

13 MR. SHANKER: Exactly. There's nothing wrong
14 with that -- when they explained why they did it it made
15 perfect sense.

16 MR. BOWRING: We've talked about how automatic it
17 might be to define what scarcity is but defining what the
18 price is during different levels of scarcity is not
19 automatic and if somebody has to say what the price is and
20 it's not coming out of the market someone has to say what it
21 is. That again has to be a rule and that's I think -- that
22 fact is a reason to think very seriously about whether we
23 want to go down that route.

24 MR. KLEIN: I think that, if you look at where we
25 are on that spectrum, are we too far over in terms of too

1 high scarcity pricing given the bid caps or too low scarcity
2 pricing? I think it's pretty clear from the evidence of
3 market performance, when we did have tight markets that, if
4 anything were on the wrong side of that one and it should be
5 higher revenue than lower.

6 MR. BOWRING: You are talking about aggregate.
7 The aggregate issue, which I identified also and I think
8 it's important not to confuse the fact that aggregate
9 revenues are low for whatever reason, whether it's your
10 market design issue or something else, or competition --
11 aggregate market revenues are low.

12 Let's not confuse that with the local market
13 power issue. That doesn't mean that doesn't have any
14 necessary implication with anything having to do with local
15 market power. It does mean that we do get wrong in local
16 market power.

17 In fact, the evidence is that we're not. The net
18 revenues of those being cost capped are about the same as
19 those not being cost capped.

20 MR. GRAMLICH: Just to clarify this question that
21 seems unresolved, there's an open question about how much
22 scarcity pricing and when. Roy doesn't want to pay
23 infinite. He doesn't want to pay \$5,000 a megawatt hour
24 every hour for the next three years before there's a
25 transmission line.

1 On the other hand, I think you acknowledge, Roy,
2 that there is some capacity value that would not be
3 reflected in a market price that cleared at somebody's
4 short-run, least-efficient units' short run marginal costs
5 for this intervening period.

6 So we have to figure out how much scarcity
7 pricing and when.

8 MR. PERLMAN: Stated another way it seems to me
9 what Joe was saying and I think Dave's agreeing is, it's
10 just a policy question. If the Commission were to involve
11 itself in saying when scarcity is and then help incentive
12 establishing or in the pricing, which is an administrative
13 structure in that arena and then having sort of amp the rest
14 of the time, which is sort of the New York model, no one
15 would accuse us of interfering with markets with that.

16 MR. BOWRING: It sure sounds like Bill's slippery
17 slope to me, but what do I know?

18 MR. HOGAN: I would make a distinction for your
19 purposes of clarity. I think what you need is clarity and
20 when market power and mitigation apply so you should have
21 some ex ante rules. I think you can make that pretty
22 transparent -- not completely but pretty good.

23 I don't agree that scarcity is a binary thing. I
24 think it's a relative thing. That means there's always a
25 mixture of both things going on and I think Joe Bowring is

1 exactly right. I didn't understand what he was saying
2 initially but I think now I agree with him when he points
3 out, "well, the demand curve for operating reserves is an
4 administratively set demand curve." Right, that's a fact.

5 And that's life. The demand curve for ICAP is
6 administratively set. Not only that, it's an administrative
7 product. It doesn't actually even exist.

8 Operating reserves are different. You can
9 actually go out and test and measure and so forth and things
10 like that are dictated by the technology because you don't
11 have the response time.

12 If we had better response times then we wouldn't
13 need it and I'd be making a different argument. That's a
14 fact that you have to have an administrative demand curve
15 and you do whether they're vertical or sloped.

16 If they're vertical then you get all kinds of bad
17 incentives, so clarity there is bad.

18 What you really want is sloped, then there will
19 be a mixture. That's the buying side. Now on the supplying
20 side that's more like a market and it may have market power.
21 Therefore you have to mitigate the market power on occasion
22 and you can have some rough rules about when you do that to
23 provide some clarity.

24 I think that's the reality so, if there is no
25 pure market solution given the technology, particularly in

1 terms of operating reserves and you just have to -- that
2 becomes the responsibility of the regulator and the ISO
3 advising and NERC conversations about what the standards
4 ought to be and where we set these demand curves and what
5 they ought to look like.

6 The same with the damage control bid cap --
7 \$10,000 would be better.

8 MR. COLEMAN: Do you even need that damage
9 control bid cap if you have amp -- can you get rid of the
10 damage control bid cap?

11 MR. PERLMAN: You need to reserve demand curves.
12 The important thing to recognize, though, is that you've
13 made a lot of these decisions. You just don't know it yet.

14 (Laughter.)

15 MR. PERLMAN: We thrash it out and say how much a
16 reserve is worth. If we're going to set a demand curve at
17 what level should we set it? You've already set it because
18 you tell the operators every day, day in and day out, "I
19 want you to accept energy up to \$1,000 to back down a steam
20 unit that partly costs \$50 or \$70 to create reserves if
21 you're going to be short of reserves. The shadow price for
22 reserves is \$900 or \$950 so you already told the ISO "pay
23 \$950, don't pay anything higher. There's an implicit value.

24 What gets lost is that, when that option isn't
25 available or when it's happening out of time in sequence,

1 like we have to accept out imports on an hourly basis but we
2 set prices on a five minute basis, there's no way of
3 reflecting that \$950 shadow cost in the energy price.

4 What happens in most of these markets is, the
5 operators press the magic red button and release the
6 reserves into the market.

7 If you had told them they should be paying \$950
8 to maintain the reserves they've just injected a \$950
9 resource into the market in order to keep the lights on --
10 in other words, lowering their operating reserve holdings.
11 That doesn't translate into energy prices anywhere and
12 that's the whole crux of the scarcity pricing.

13 The important thing is that all your decisions be
14 logically consistent with one another. If you decide
15 reserves aren't worth \$950 you need to rethink the safety
16 net bid cap in making sure everything is working together in
17 a consistent manner.

18 MR. COLEMAN: Thank you.

19 Since we've gotten back on time, with time
20 management, I want to thank everyone for a very lively and
21 useful discussion. We will break now until one-thirty.

22 (Whereupon a luncheon recess was taken at 12:10
23 p.m.)

24

1 A F T E R N O O N S E S S I O N

2 1:35 p.m.

3 MR. COLEMAN: If you'll take your seats, we're
4 going to get started here.

5 This afternoon we have two panels, the first
6 panel is going to be focusing with a little more granularity
7 than I think this morning on some of the RMR experiences in
8 the Northeast.

9 One housekeeping matter before I turn it over to
10 the speakers -- a number of speakers have been working from
11 presentations this morning and brought copies and some have
12 been distributed.

13 We'll be sending out a follow up e-mail to all of
14 you asking you to send us an electronic copy of your
15 comments so we can post them on our website under the
16 technical conference so that we will be certain that
17 everyone will have an opportunity to view what you have to
18 say.

19 This afternoon's format, we're asking speakers to
20 try to limit their comments to five minutes. We will follow
21 the same format as this morning with a Q&A session from
22 Staff and the Commissioners.

23 Our first speaker this afternoon is John
24 Anderson, Managing Director and Head of Power and Project
25 Finance at John Hancock Financial Services.

1 Welcome, John.

2 MR. ANDERSON: Thank you, Mr. Coleman.

3 I'll really focus my comments as an introduction
4 on who John Hancock is and our investments in the power
5 sector. I think you'll find that we're very representative
6 of a large base of investors that some of the speakers spoke
7 to this morning.

8 Hopefully I can amplify that in a first person
9 kind of way as one participant in the debt market for power.
10 By way of introduction, our perspective at Hancock is
11 unusual in that we have a large and very diverse investment
12 portfolio in the power sector. I manage an investment team
13 at Hancock with an \$8.5 billion portfolio in power.

14 One of the things that is noteworthy about our
15 portfolio is that we're spread across a wide range of
16 sectors in the industry. We have a large portfolio of loans
17 to regulated utilities directly. We also have investments
18 in utility holding companies but also most of our
19 investments are on the unregulated side.

20 So if you looked at my portfolio, the largest
21 single area of my investment has been in independent power
22 projects where we've invested in companies that are
23 essentially taking the risk that they can perform to a long
24 term contract to a regulated load serving entity. That's
25 been a very opportune and good fit area of investing for us.

1 The reason that we like the power industry and
2 that asset space is that, generally speaking, on the
3 regulated side, it's been nice and stable and we've had good
4 performance from our portfolio and one of the reasons that
5 life insurance companies like the power industry is that the
6 assets have very long lives and, if we're rating 30 year
7 life insurance policies on one side of our business, we want
8 to find an industry that we can invest into that can provide
9 stable returns over a similar life and power assets have a
10 lot of those features.

11 In many ways we feel that we're a natural
12 ultimate investor for power generation assets and power
13 infrastructure. Many of the comments that you heard this
14 morning I think echo that. Not surprisingly I think it is
15 an important source of capital.

16 Most capital for power infrastructure is provided
17 by debt markets not equity markets. If you look at
18 capitalization of power assets, as you probably heard this
19 morning, we value stability. We're not in this to make a
20 killing off of spiking peak power prices. We're putting
21 capital into this business in opportunities that we think
22 can provide long term stable reasonable returns and are on
23 the low end of the risk adjusted spectrum.

24 With that as an introduction I am happy to
25 provide any comment on further topics of interest but I

1 thought that would be a good way to start off, just to
2 introduce the perspective we bring.

3 MR. COLEMAN: Thanks, John.

4 We're going to move to another member from the
5 financial community, actually someone who was on our first
6 panel, but we'll give Jonathan Baliff an opportunity to
7 provide some additional comment on behalf of CSFD.

8 Jonathan?

9 MR. BALIFF: Thank you again. What I wanted to
10 get into at least in the afternoon is a little bit deeper
11 examination of just really how do you finance a specific
12 generation project or a specific project to alleviate some
13 of the load or RMR concerns that Credit-Suisse First Boston
14 is the financial advisor.

15 One is SES, that is, the name of the developer,
16 Astoria. SES Astoria is a 500 megawatt gas-fire combined
17 cycle plant in the Astoria load pocket very close to
18 LaGuardia Airport. If you ever come out of LaGuardia and go
19 towards the City you'll basically pass this facility. It is
20 on a 23 acre site very close to a substation.

21 The second project that we'll get into which was
22 mentioned by Abram -- basically that's a 1,000 megawatt BC
23 intertie between Upstate New York and is in the middle of
24 financing.

25 Both these projects right now are in the middle

1 of what we call the "financial sales process." We are going
2 out to investors to basically sell the debt for these
3 projects. They are right now being sold as, not corporate
4 projects, but as asset projects.

5 What do I mean by that? The debt investors will
6 get security. They will own the asset.

7 In the down side scenario, if the privates don't
8 perform, they will take the asset themselves and try to do
9 something with it. That's what's called a "secured asset."

10 Both of them are going to be financed in that way
11 so that we're not looking for any corporate parent to be
12 able to provide any guarantees.

13 Let's go to SES Astoria. The primary way we sold
14 this asset is that it has a first mover advantage. That is
15 the most important way to sell an RMR or load pocket project
16 and it's obvious it can't take so many projects. You only
17 need one or two at the most, maybe even just one.

18 There's a debate obviously with some of the
19 gentlemen who were here before on how the actual market is
20 going to work. The financial guys just want to know are
21 there going to be sustainable cash flows here, the way we
22 sold and the way we are selling SES is, "yes."

23 There is a first mover advantage. This will be
24 in the Astoria load pocket. It will crowd out virtually any
25 other significant project in that area and also affect the

1 ability for anybody else to come in and steal the economic
2 lights.

3 Although that sounds a little bit pejorative,
4 we're a bank. We're trying to sell our client to these
5 investors. One of the other ways that we sell it, as I said
6 very briefly, there are five risks that all the investors
7 look at in these types of projects -- construction risk,
8 market risk, operational risk, fuel risk and regulatory-
9 political risk.

10 You must have answers to all five of those
11 questions. If you're going to face somebody like John
12 Anderson who, I can tell you, will grill you for at least an
13 hour and then you can have conference calls with him
14 throughout the sales process on and on.

15 This is a big amount of money that these guys are
16 going to be putting to work.

17 Let me talk about market risk. The debt
18 investors will not take market risk right now. They'll take
19 a little bit of market risk but they're not going to
20 primarily take most of the market risk and what do I mean by
21 that?

22 In the first five to 10 years, it's debt. Better
23 amortize -- i.e., book most of the debt better be paid off
24 before in a load pocket entity before a debt investor will
25 take any money and put it in.

1 So we need to have a contract. That was almost a
2 necessary but not a sufficient condition to get this
3 financed and you need to have a credit-worthy off take.

4 What we mean by that is an investment grade
5 triple B minus or above -- and I would say, today -- and
6 correct me if I'm wrong -- you probably want higher than
7 that?

8 MR. ANDERSON: Right.

9 MR. BALIFF: We want to see somebody like a Con
10 Ed, who is an A rated entity come in and give us a nice 10
11 year contract. I'm not going to get into the details of
12 what that contract is but, for the most part, it needs to
13 create a stable cash flow stream.

14 I'm not going to get into operational risk
15 because most everybody knows these CCs or the combined
16 cycles are normally very standardized technology like G-E
17 Frame 7s, very easy to operate. Fuel and operability must
18 be done under not as long a contract, but it can be done
19 under a shorter contract. But it must be handled.

20 Finally, the regulatory and political risk
21 combined with the construction risk are not mutually
22 exclusive, especially in load pockets.

23 What we are selling the investors is, from a
24 political standpoint, the project has tremendous political
25 advantages with both the city councils, both the borough

1 presidents and we're looking at investors who might even go
2 talk to the Borough President of Queens to understand what
3 this project means to them.

4 Why? Because construction costs are mostly time
5 sensitive. What do I mean by that? We set down a pro forma
6 projection based on the time it would take to construct
7 given the nature of trade costs in New York City. Time not
8 only is money -- time is blood, sweat -- it's everything if
9 this thing starts getting delayed.

10 We consider a project to go approximately \$1.0
11 million per month on just construction and labor alone.
12 That is a very big part of what we need to get settled out.
13 We expect that SES will be financed in the next two weeks.
14 We've pretty much got the debt financing lined up with
15 institutional investors that I talked about this morning.
16 The equity is going to be provided by very nonstandard
17 equity providers.

18 What do I mean by that? No strategic equity.
19 It's going to be provided by private equity and some of the
20 same people who are in the debt are going to provide the
21 equity in the project itself, so I take questions on SES and
22 Astoria -- and also conjunction since my time is short --
23 but conjunction is being financed in a very similar way.

24 Thank you.

25 MR. COLEMAN: Thanks, Jonathan.

1 Next, we have Mark Reeder from the New York
2 Public Service Commission. Welcome, Mark.

3 MR. REEDER: Thank you very much for giving me
4 the opportunity to share my thoughts here today.

5 The qualifier is, these are my thoughts and not
6 those of the New York Public Service Commission. I was
7 asked to focus my comments on the capacity market demand
8 curve. There's a fair amount of discussion of it this
9 morning. I'm just going to try to gather together in the
10 short amount of time I have.

11 (Slide.)

12 I did bring copies of an affidavit that Dr.
13 Thomas Painter of our staff filed with FERC in April which
14 explained the whole thing. It was designed to be self-
15 contained. If anyone didn't get a copy of that, that would
16 help. I can't cover it all in five minutes but I'll just go
17 through the highlights.

18 The motivation for the demand curve came out of
19 two pretty big problems that we had with the capacity
20 markets. The first one is that they had this boom and bust
21 cycle. The parties called it "falling off the cliff."

22 If you got a little bit extra the price would
23 just crash. Because the purpose of the demand curve -- I'm
24 sorry, because the purpose of the ICAP market was to provide
25 this extra revenue stream to help get entry and then we talk

1 to bankers and we see people saying "the revenue stream is
2 discounted to next to nothing because of how volatile it is
3 -- it seems to be dysfunctional, so the demand curve is
4 priced to smooth out that revenue stream over time to keep
5 the lows from being as low -- keep the highs from being as
6 high.

7 The second big problem is, we felt there was a
8 very strong volatility to market power in the capacity
9 market. With a little bit of excess withholding could drive
10 you to a shortage and send the price through the roof and we
11 did experience that once in New York and it wasn't a
12 pleasant experience.

13 So if you could flatten it out with the demand
14 curve you could make the revenues more stable over time from
15 the perspective of the generation developers and protect
16 against market power from the perspective of the consumers,
17 so that's really where it came from.

18 It had one additional feature that was nice and
19 that is, we felt pretty strongly that, if you had 118
20 percent reserve requirement, that 119th percent isn't
21 completely worthless from a reliability standpoint. Having
22 a little more is okay and it does help reliability.

23 So it didn't make sense for the system to have a
24 willingness to pay -- this is this vertical demand curve, I
25 think, as Mr. Gramlich mentioned, that says "we'll pay

1 absolutely everything up to 118 and absolutely nothing from
2 119.

3 It didn't seem that the system should express
4 that willingness to pay so we put in a demand curve, look at
5 the graph that's on the screen -- and that graph, 118
6 percent, is the point that denotes the required reserve
7 margin. That's the one that equates to one day in 10 years'
8 reliability.

9 There used to be a vertical demand curve right at
10 this point. Like a demand curve does, it just puts a sloped
11 curve through that same place and one of the keys is, you
12 have to decide how high to make it. If I have time I'll get
13 to that later.

14 But what you can see here is, at the 118 percent
15 point the price here is \$56 per kilowatt year, a little bit
16 more, say 120 percent -- price doesn't crash, it drops down
17 the curve to \$48.

18 What that does is produce much more stable
19 revenue streams in times of moderate amounts of surplus. It
20 avoids the crashes and also, as was mentioned earlier today,
21 if someone withholds to drive you from 120 percent back to
22 117, instead of going way up to a deficiency charge that's
23 quite punitive, you just slide along the curve there also.

24 That removes the extent to which price jumps in
25 response to withholding. That merely knocks a hole in the

1 profitability of the economics of a player considering
2 withholding. It takes the incentive to withhold away or
3 greatly reduces it.

4 So that's the basic reason we proposed it and the
5 parties basically went for it because it seems to accomplish
6 those goals and those are real important goals.

7 There's a third goal that wasn't really mentioned
8 earlier today and that is that the curve has to be steep
9 enough so that, if you offer this extra money and you get
10 tons of capacity, you don't end up just having way too many.

11 If you get quite a bit too many the curve drops
12 down and the price drops to choke off the problem of excess
13 supply. Determining the height of the curve, I'll just have
14 a brief amount of time. This is a key parameter. People
15 talked about this as an administratively determinate thing
16 and it is -- at the 118 percent point the height of the
17 curve should be an amount, or it starts off at the amount
18 that a generator needs to cover its capital costs after
19 considering the fact that it gets revenues from the energy
20 and ancillary service markets.

21 So it's the net revenues. It still needs on top
22 of what it gets from the energy ancillary service markets
23 and what we thought was important to do, is to decide what
24 that number is but set the curve higher than that to err on
25 the side of reliability, if you will.

1 For example, if you thought it was \$50 on this
2 graph that we were looking at and it turns out so you set
3 at, say, \$56, if it turns out the cost of entry is only \$48,
4 entrants may come in so long as they can get more than 48
5 and drive you to the right along the curve to point B on the
6 graph and you may settle out at a price of \$48, so that the
7 mistake of setting it too high is, you end up getting a
8 little too much. You might get 120 percent instead of 118
9 percent and pay \$48.

10 So it seems to make sense to err on that side.

11 So just to summarize, from a consumer point of
12 view, it is very valuable. It protects against the market
13 power but it also takes this big chunk of money you're going
14 to give out over 20 years in the capacity market and
15 provides it in a more stable way so you buy more entry for
16 the same amount of money over time.

17 So in the question and answer period we can
18 discuss some more pieces of it because there are a lot of
19 other pieces of it. But basically I think that's really
20 what there is to it.

21 Thank you.

22 MR. COLEMAN: Thanks, Mark. Certainly we'll get
23 into a few more questions on that in the Q&A.

24 Next we have Steve Wemple from Con Edison.

25 MR. WEMPLE: Thank you, Michael.

1 Good afternoon, Chairman Wood, Commissioner
2 Brownell, Staff -- my name is Stephen Wemple, Director of
3 Retail and Regulatory Affairs for Con Edison Energy, which
4 is a subsidiary of Con Edison, Inc.

5 I am appearing to day before the Federal Energy
6 Regulatory Commission on behalf of the Edison Electric
7 Institute and it's affiliated Alliance of Energy Suppliers,
8 a division of the EEI that specifically represents power
9 suppliers and also on behalf of Con Edison Energy.

10 Con Edison Energy and its affiliates, Con Edison
11 Solutions and Con Edison Development, are active in the New
12 York, New England and PJM energy markets and own over 1,500
13 megawatts of generation and supply approximately 1,500
14 megawatts of retail load in New York, New Jersey and
15 Massachusetts.

16 First I would like to commend the Commission for
17 accepting the recommendations of EEI, PJM and others to
18 convene this technical conference. The first part of my
19 remarks address EEI's position on this topic, with which Con
20 Ed Energy fully agrees.

21 Before concluding I will also share Con Ed
22 Energy's perspective based on our own experiences owning and
23 operating peaking units and hedging retail load in the
24 Northeast.

25 EEI believes that generators must be adequately

1 compensated when required to provide the reliability
2 services necessary to support the electric system. In fact,
3 the Commission has an obligation to adopt rates that are
4 just and reasonable for consumers and generators.

5 Consistent underrecovery of investment dollars
6 which has been occurring in the New England and PJM markets
7 will naturally lead to reliability problems as owners are
8 forced to defer maintenance on or retire existing generating
9 units.

10 The problems EEI is concerned with is the need
11 for a reliability "must run" contract is indicative of a
12 failure in the design of the local markets to provide
13 adequate compensation for units needed for reliability.

14 If the existing market rules are not providing
15 adequate compensation the ISO or RTO should determine that
16 the need for design changes that can provide adequate
17 compensation and work with stakeholders to effectuate the
18 necessary changes.

19 EEI's preference is for a market based solution
20 to determine appropriate compensation in the absence of
21 market solutions. EEI believes that out of market
22 intervention is appropriate to ensure reliability and that
23 such intervention must be structured to provide adequate
24 compensation to the extent possible to emulate a competitive
25 market based solution.

1 Because many of the units considered for RMR
2 treatment are located in areas where there is limited
3 transmission and/or generating capacity there are concerns
4 that such units could exert market power absent some form of
5 negation in situations where there is a demonstrated concern
6 about market power.

7 Monitoring mitigation or other measures may need
8 to be considered to restrain the exercise of market power.
9 In such instances, the RTO ISO needs to establish and
10 publish a clear objective standard on what constitutes
11 market power and the criteria for imposing mitigation.

12 However, mitigation measures have to be
13 structured in such a way that they do not discourage the
14 long term investment signals and must not deprive existing
15 owners of the opportunity to recover all long-run marginal
16 costs including variable and fixed costs.

17 For example, mitigation units' bids to variable
18 production costs will deny that unit any opportunity to
19 recover fixed costs from the energy market.

20 In addition, if a region does not have sufficient
21 supplies to meet its load and reserve requirements, then
22 market rules and mitigation measures in particular should
23 not set prices artificially low and suppress the natural
24 price signal that supplies are scarce.

25 Ultimately EEI believes that a market that is

1 able to attract and retain necessary resources, local or
2 delivered generation and demand response without the use of
3 subsidies is in the consumer's best interest because it
4 provides a long-term solution to relieve market power
5 concerns, maintains reliability, produces just and
6 reasonable rates and enhances quality of service.

7 The design of RMR and mitigation measures needs
8 to offer variation, including regional ones, due to
9 differences in resource mixed cost structures and operating
10 requirements. The costs associated with RMR mechanisms
11 should be borne locally and preferably conveyed through well
12 designed existing mechanisms such as capacity and/or energy
13 market pricing.

14 This allows loads to either react to the price in
15 the local reliability need with demand response measures
16 and/or be able to hedge their costs through purchases of
17 capacity and energy.

18 With respect to capacity markets, EEI believes
19 that a variety of mechanisms will allow RMR generation to
20 obtain adequate compensation. For example, properly
21 structured regional capacity markets with deliverability
22 requirements and properly structured locational capacity
23 markets.

24 Finally EEI believes the market monitor needs to
25 be truly independent of the markets they monitor and have a

1 screening but not determinative role in establishing the
2 need for mitigating RMR units. The ISO RTO is not -- the
3 market monitor should decide how to implement RMR
4 mitigation. EEI believes mitigation rules and
5 implementation procedures need to be clearly articulated in
6 tariffs filed with and approved and accepted at the
7 Commission.

8 I'd now like to take a moment to share Con Ed
9 Energy's experiences as the owner of peaking units in New
10 England and PJM. Con Ed Energy --

11 MR. COLEMAN: Make it brief, Steve.

12 MR. WEMPLE: Very brief, Michael.

13 Con Ed Energy believes that the problems facing
14 RMR units are symptomatic of issues facing the overall
15 energy markets, in particular, PJM and New England. Last
16 summer I performed an analysis of prior PJM state of the
17 market reports, presented the results to PJM and included
18 them in our October 30th comments on the proposed PJM
19 mitigation plan.

20 My analysis indicates that the net revenues for
21 peaking units were overstated in each of these reports since
22 1999, which makes the revenue shortfall worse than has been
23 reported. From 1999 through 2002, peaking units have only
24 recovered 70 percent of their required revenues.

25 Last year was even worse and the forward curves

1 indicate that 2004 and 2005 will only provide 30 percent of
2 the requirements. This means that existing units may not be
3 able to afford normal maintenance and no new merchant plants
4 will be built without significant market reforms.

5 PJM and the other regions need to focus on
6 solutions to these problems and solutions include
7 compensating units that provide 10 minute non spin and 30
8 minute reserves and if there are local requirements, local
9 markets for those services, too -- establishing scarcity
10 pricing rules so that when on short on energy and reserves
11 or using block loaded units or making emergency purchases,
12 energy prices are not set artificially low by on-line units
13 and reform the capacity markets to value resources in excess
14 of minimal requirements as we've heard other speakers say
15 and, from an LSE's perspective, RMR funding mechanisms
16 should work through existing capacity and energy markets
17 where practical to avoid unhedgeable costs.

18 Out of market payments for RMR units that create
19 unpredictable uplift costs are harmful to retail markets as
20 they create uncontrollable financial risks for LSEs.

21 Thank you.

22 MR. COLEMAN: Thank you, Steve.

23 Next we have Richard Rapp from KeySpan Energy.

24 Richard?

25 MR. RAPP: Good afternoon. Thank you for

1 inviting KeySpan to participate in today's conference. I'm
2 here on behalf of KeySpan Ravenswood, which owns and
3 operates approximately 2,200 megawatts of generating
4 capacity in New York City -- the "New York City" often
5 referred to as "Zone J."

6 In addition we are in the final stages of
7 completing the 250 megawatt combined cycle unit which should
8 be on line in the next several weeks.

9 Energy resources including generation,
10 transmission and demand response require just and reasonable
11 compensation if they're going to provide the services
12 required to meet the needs of customers in bid-based
13 markets.

14 Moreover the needs of customers should be
15 established using mandatory reliability requirements.
16 Otherwise, investors will be unaware of the potential
17 necessary infrastructure enhancements. Once mandatory
18 reliability requirements are established, a market design
19 that provides an efficient price signal for investment to
20 meet these reliability requirements is required.

21 In a bid-based market that price signals should
22 be as uniform as possible to all market participants -- in
23 other words, the same price signals should be provided to
24 all providers providing the same service. If the market is
25 designed properly it should provide sustainable price

1 signals that will encourage the investments required to meet
2 reliability requirements and RMR contracts should not be
3 required.

4 Such a market design would include a stable
5 capacity market including locational requirements as
6 necessary locational based marginal priced energy and
7 ancillary services such as operating reserves.

8 Opportunities for the participation of demand
9 response and appropriate scarcity pricing mechanisms are
10 also an important aspect of an efficient and successful
11 market design.

12 KeySpan recognizes that, even with such a market
13 design, there are concerns about potential local market
14 power and reasonable rules and regulations such as
15 mitigation measures may be required in certain markets to
16 protect against the potential abuse of market power during
17 the continuing evolution of competitive markets.

18 However overly intrusive and excessive mitigation
19 can result in the distortion of price signals that the
20 market requires to ensure new and existing resources are
21 available for reliability.

22 In addition, mitigation measures should be
23 balanced and applied uniformly to all market participants
24 including purchasers. It is not only suppliers that may
25 have potential market powers. Purchasers that have

1 monopsony power can distort markets and abuse market power
2 as well and can cause prices to be depressed from otherwise
3 competitive levels if markets are not designed
4 appropriately. Bid-based market designs must therefor
5 account for and anticipate both possibilities.

6 Local market power is difficult to define
7 precisely. In general, KeySpan uses market power as the
8 ability to increase or decrease market prices from
9 competitive levels in a predictable and sustainable manner.

10 In a properly designed based market local market
11 power should not be a concern and targeted mitigation
12 measures can effectively prevent potential abuse.

13 For example, unit specific bid caps based on
14 costs can prevent individuals from increasing market
15 clearing prices, locational based marginal prices assure all
16 resources are paid the same competitive price.

17 We share the view that RMR contracts are the
18 result of market failure and should only be utilized as a
19 last resort. RMR contracts can further distort market price
20 signals unless the market design is revised such that the
21 RMR contract is somehow reflected in market prices.

22 Buyers and sellers need to see an efficient price
23 signal to prevent further market distortions. RMR contracts
24 or other out of merit resources should be permitted to set
25 clearing prices in appropriate circumstances such as when

1 markets are short capacity or operating reserves.

2 It is important that market prices reflect RMR
3 contract costs in these situations notwithstanding potential
4 market power concerns. Otherwise the need for RMR contracts
5 would be perpetuated and reliability could be jeopardized
6 because new resources will not have an efficient price
7 signal in which to respond.

8 Additional infrastructure should not be forced on
9 the market to mitigate potential market power concerns,
10 eliminate load pockets or mitigate prices. If efficient
11 economic signals exist, which are the result of achieving
12 mandatory reliability requirements, investments in
13 generation transmission or demand response will be made
14 where appropriate.

15 Cross based regulated infrastructure intended to
16 eliminate congestion, mitigate purported market power or
17 resolve load pockets should not be made in a competitively
18 based market.

19 Cost based regulated infrastructure intended to
20 eliminate congestion may in fact not eliminate it. It might
21 merely impose the additional cost of the regulated
22 infrastructure on consumers. If congestion costs in fact do
23 not go down as the result of the regulated infrastructure
24 consumers are then faced with paying for the regulated
25 infrastructure in addition to the congestion costs. In some

1 instances it could very well be the congestion costs
2 represent the least cost solution for customers.

3 Addressing quickly spot market price mitigation,
4 in general KeySpan does not think spot market energy price
5 mitigation is efficient or necessary. ISOs can keep up with
6 changes that occur on an hourly basis in real time markets
7 with respect to fuel costs, opportunity costs, risk and
8 other real time events.

9 Gas market real time prices are not mitigated and
10 they have a significant impact on real time energy cost.
11 The real time energy market is essentially a balancing
12 market that should not be mitigated.

13 The volumes transacted, the quantity of supply
14 and the inability to predict real time markets argue against
15 mitigation.

16 I also have some prepared remarks that I have put
17 in written form. As well, as I was going to address some
18 regional issues related specifically to the New York ISO.
19 I'll save that for the discussion portion.

20 Thank you.

21 MR. COLEMAN: I appreciate that, Richard.

22 Next we have Jonathan Falk from NERA.

23 MR. FALK: I want to thank the Commission for the
24 opportunity to share my views on when and how the RTOs
25 should deal with local market power concerns.

1 First however let me say my presentation is being
2 sponsored by the marketing and generation organizations of
3 PPL Corporation. PPL is a member of PJM and one of its
4 original founders. It operates several generating units in
5 PJM which have been subject to offer capping and one in New
6 England, the Wallingford facility, with which I suspect the
7 Commission is somewhat familiar. PPL also owns and operates
8 generation in Maine, New York, Montana, and Arizona and
9 distributes electricity to 1.3 million customers in central-
10 eastern Pennsylvania.

11 I want to focus my remarks today on the first
12 question FERC posed in its cyclical conference agenda. What
13 is local market power? Why should it be mitigated?

14 I have come to the conclusion that a lot of the
15 controversy that this question has caused is a direct result
16 of not really thinking about this question in the
17 appropriate context.

18 The insight I have had and I hope you will agree
19 that it's a useful insight, is that local market power is
20 simply the ability to collect a locational rent, that is,
21 it's an opportunity for economic profit that flows from the
22 fact that certain units at certain times are much more
23 valuable than other units.

24 The value stems from the fact that, without them,
25 the reliability of services is threatened and reliability is

1 very, very valuable. There is no other rent that we don't
2 allow generators to try to capture. If they can generate
3 very cheap power we let them capture the difference between
4 their costs and the market price.

5 If they have savvy trading operations we let them
6 earn as much profit as they can on that operation. If
7 they've signed contracts that turned out to be priced above
8 market price over time we let them keep those profits.

9 Why do we even call these locational rents
10 "market power?" I think the reason is that we've been too
11 focused on the technical definition of market power as the
12 ability to affect price. This definition is not helpful as
13 a practical guide in two respects.

14 First, to be accurate, it has to be conjoined
15 with the notion of sustainability. That is, market power is
16 an ability to significantly affect prices which cannot be
17 thwarted by entry or by actions of other current market
18 participants.

19 We focus on affecting price but we tend to wave
20 our hands when considering the effect of entry on the
21 sustainability on the price increase except we sometimes
22 assert that entry would take "too long," whatever that
23 means.

24 The second reason which -- the first I think
25 we've talked about before. The second reason is even more

1 pervasive. We don't really ask what it means that the unit
2 in question can affect price. The only reason that it can
3 affect price is that it's output is more valuable than
4 another unit's output to fulfill the local reliability
5 function.

6 This is a good thing and it ought to be
7 encouraged with at least some level of rents to induce
8 others to enter in an attempt to capture those rents.

9 Why do some think that locational rents are
10 different from the rents that come from fuel cost
11 differences, favorable rent times or any other host of
12 things which make some generators perform better than
13 others. I think there are three main reasons.

14 One, the rents which are earned from location
15 aren't really earned. They represent historical accident
16 and thus would just be a windfall to the person who happens
17 to own the unit.

18 Two, load pockets aren't readily susceptible to
19 new entry, or, three, the loads inside the load pockets are
20 captive customers who deserve protection.

21 None of these reasons, however, are without
22 weaknesses which, when carefully considered, undermine their
23 superficial appeal considerably.

24 First, even if the initial distribution of these
25 rents may be accidental -- and for recently constructed

1 generators in expensive load pockets like PPL Wallingford,
2 they shouldn't be considered accidental -- the whole point
3 of generation competition is to generate better patterns in
4 the future. Leaving some level of rents out there for
5 generators to potentially capture is the price we pay for
6 dynamic efficiency, just as all the other rents which a
7 generator can earn from, say, a reduction in its heat rate
8 promotes that sort of innovation.
9
10

1 Second, while there may be some load pockets for
2 the barriers to go into that really are structural. This is
3 the point a lot of people made this morning. We know very
4 little about what changes the transmission infrastructure or
5 what entry decision could completely eliminate the incumbent
6 generator's locational rent.

7 The New England Committee experiment, which I
8 assume we'll discuss a little more, is quite instructive in
9 this regard. They're not as reliable. As a matter of fact,
10 competitive systems are very good at arbitrating rents. We
11 ought to give them at least an opportunity to try.

12 Third, as to the protection of captive customers,
13 if the barriers really are structural, and if competition
14 can really solve these problems, the customer should need no
15 more than temporary protection and to achieve the dynamic
16 effects we have to loosen the constraints on price. The
17 line between gouging and incentives is one regulators will
18 have to draw but it makes no more sense for customers to
19 keep these rents than generators. And if we use the analogy
20 of market power to try and cap these prices at short run
21 variable costs we shouldn't fool ourselves into thinking
22 that we're doing anything other than allowing loads to
23 capture these rents by allocating these rents to consumers
24 at the expense of generators. We not only give no incentive
25 for anyone to relieve the constraint, through new investment

1 or load response, we actually give consumers incentives to
2 locate within the load pockets and make their problems
3 worse.

4 The upshot is the operation of the electric
5 system is producing locational rents whether regulators have
6 realized it before or not. They're going to have to decide
7 how to allocate the locational rents. That's a simple fact.
8 Giving some of those rents to generators, i.e., allowing
9 them to use some of their so-called "market power" is the
10 only way to keep these temporary problems from becoming
11 permanent.

12 As a final point, if we decide for whatever
13 reason that a load pocket is chronically in need in
14 mitigation, and, of course, there could be some, we would be
15 better served finding a market mechanism to replace
16 indefinite administrative oversight and the reposed PPL
17 auction mechanism. PJM provides that necessary fall back
18 mechanism in those remaining situations that markets can't
19 correct.

20 I'd like to thank the commissioners, commission
21 staff and those of you in the audience. I'll answer any
22 questions that I have. Both this and the long version of
23 that are available for anyone who wants to read it.

24 MR. COLEMAN: Thank you for being brief. Next we
25 have Steve Corneli of NRG Power Marketing.

1 MR. CORNELI: Thank you, Michael. Thank you to
2 the Commission for having us here today to address these
3 really important issues of RMR conditions, compensation and
4 the relationship to market power.

5 NRG owns significant amounts of competitive
6 generation in the constrained areas of PJM, New York and
7 NEPOOL. I guess you could say we're intimately familiar
8 with mitigation, RMR issues and related market design needs.
9 We really appreciate this opportunity to talk to you about
10 those issues.

11 As I've listened today, I think I've discerned
12 that the real theme of this technical conference is maybe
13 what is the critical policy issue facing these areas and it
14 seems to me that what a lot of people are saying is that the
15 critical policy issue is not the mitigation of market power
16 and trying to keep prices from being too high. It's the
17 mitigation of market design flaws that are keeping prices
18 too low.

19 I want to talk about four points, I think, that
20 address the topics for this panel and that reflect some
21 things that other folks have said today that illustrate
22 those needs and the potential solutions.

23 The first point, there is really good evidence
24 that the exercise of market power is not taking place in any
25 of these three markets in the Northeast. That's good news.

1 It does suggest that we need to focus not so much on the
2 exercise of market power as something else. The definition
3 of market power as other panels have said is when sellers
4 have the ability to raise and profitably sustain prices
5 above the competitive level. I submit to you that there is
6 no better indication of the competitive level in area that
7 needs new resources than the long run marginal cost of
8 investment in that region.

9 Each of the three market monitors for each three
10 northeastern market areas annually puts forth a state-of-
11 the-market report that shows and has consistently shown that
12 in new place can new entrance recover more than their long-
13 run marginal costs. Indeed, in most of the constrained
14 areas, they recover considerably less in the market. That
15 means there is no market power being exercised. It might be
16 that Bob and his colleagues are doing an excellent job or it
17 might be that market power is not quite the big problem that
18 everybody thought it was.

19 Whatever the cause, and I'll go to that in a
20 moment, the implication is startling and I think very clear.
21 For the Commission, the ISOs and the rest of us, the
22 critical policy need is not the mitigation of market power,
23 it's the correction of market flaws that create persistent
24 under recover of costs by needed investment, existing and
25 new. If not corrected these flaws will threaten

1 reliability. They'll increased consumer costs and they'll
2 threaten the future of a competitive electric industry.
3 These are problems that should concern everybody in this
4 room no matter what side of the market they sit on.

5 Second point, it's increasingly clear that
6 aggressive mitigation is not really needed to prevent
7 generators in constrained areas from exercising market power
8 and creating monopoly rents. In fact, if there's one lesson
9 from the Commission's very interesting experiment in push
10 bidding in Connecticut and Boston. This is it. Generators
11 were allowed to bid at much higher levels than they ever had
12 before, yet they were unable to recover their fixed costs.
13 Again, the policy focus needs to shift from prices that are
14 too high due to market power in to prices that are too low
15 due to market design flaws.

16 Market power is associated with extraordinary
17 profits and barriers to entry. Market design flaws that
18 we're seeing; particularly in NEPOOLm are associated with
19 extraordinary losses and barriers to exit. The NEPOOL
20 market sends price signals that tell needed generators that
21 should exit the market, retire or mothball. Yet, the NEPOOL
22 market rules are reading like the fine print on the back of
23 the door of the Hotel California. You can check out any
24 time you like, but you can never leave this market. As long
25 as this is the case, the Commission will have to recognize

1 that both existing and new investment need out of market
2 mechanisms to recover fixed costs.

3 The clear message is to allow fixed cost recovery
4 and encourage a rapid move to correction of the design flaws
5 that have prevented fixed cost recovery. Instead of putting
6 up a fence to keep the guests from leaving, it would be much
7 better to put up a market design platform that makes
8 generators want to get in rather than get out.

9 The third point I want to make, and it'll
10 probably be my last one, is that there's some good news.
11 Despite the serious design flaws, tried and true market
12 solutions do exist. New York ISOs combination of mitigation
13 and other measures have produced a moderate level of
14 scarcity pricing, a locational capacity market and a demand
15 curve for capacity which was championed with vision and
16 leadership through the New York Public Service Commission at
17 the state level. All work together and have the potential
18 to send the needed, long on-marginal cost signal to buyers
19 and sellers alike.

20 And while these elements need some fine tuning,
21 perhaps, they're already helping send signals to buyers that
22 they would have an interest to issue RFPs and enter the
23 long-term contracts like the gentleman from the financial
24 community described at the beginning of this panel. These
25 same basic design elements can work and will work in NEPOOL

1 and PJM as well and they will help induce a competitive mix
2 of infrastructure that will minimize the cost of
3 infrastructure and electric services in those markets. But
4 to get there, the Commission has to act decisively to
5 correct these design flaws really before it's too late.

6 I'll stop there and look forward to your
7 questions.

8 MR. COLEMAN: Thanks, Steve. Next we have Bob
9 Ethier, Market Monitor for ISO New England.

10 MR. ETHIER: Good afternoon. Thanks for the
11 opportunity to address you all and share our experiences in
12 New England. This morning as I was sitting through the
13 discussion it occurred to me that those of us from New
14 England are especially well-qualified to speak here in front
15 of you today because we've experienced, either implemented
16 or had on the design boards probably more types of local
17 market power mitigation than all the ISOs combined. It's
18 not something we sought to do but that's where we are.

19 This has occurred because we do have two
20 significant load pockets in New England and we've learned a
21 lot of lessons from being there. I think the morning
22 sessions did a very good job of covering the broad
23 groundwork. I can't agree more with the idea that we need
24 to get the prices right. What I want to do this afternoon
25 in these short remarks is sort of highlight a few areas

1 where I think deserve special emphasis in front of you all
2 today.

3 The first one is that New England has a clear
4 market design problem. We recognize that. We're working
5 very hard to solve that problem. Why do I think we have a
6 design problem? The design problem is evident because we
7 have units in areas that are critical for reliability but
8 want to retire. That's a very basic test. If the units
9 that you really need to have around aren't incented to stay
10 around in the market, then we need to evaluate how you've
11 structured your market design.

12 I think one of the things that we've learned from
13 our markets is that local market power mitigation does not
14 stand on its own. You can't talk about it in isolation from
15 the rest of your market design. It's really integral to
16 your market design just like a capacity market may or may
17 not be just like reserved markets, just like a locational
18 energy market. The push bidding our current local market
19 power mitigation measure, we frankly learned a lot from that
20 and I hope all the ISOs have learned a lot from that
21 mechanism. It was, I think, probably the appropriate policy
22 decision at the time given the constraints that we were
23 facing, but it is not a long-range solution, in my view.

24 In my view, a local market power mitigation
25 measure that also seeks to provide full revenue recovery for

1 RMR-type units is unlikely to work in all or even most
2 circumstances because it hasn't work in New England. So one
3 of the short answers for why it hasn't worked is there's not
4 sufficient market power to allow it to work, which is sort
5 of an interesting consequence. There are a subset of units
6 that it could probably for but the report that we've put out
7 this fall shows, I think, very clearly that it did not work
8 for the broad cross-section of units that we have determined
9 are needed for reliability that are not able to recover even
10 necessarily the going forward costs under a relaxed bid
11 mitigation regime.

12 While it may be an appropriate short-term fix, I
13 don't think it's the right emphasis for anyone to seek as
14 the long-term remedy to how do you incent folks to build in
15 load pockets. There are sort of two reasons why it's not a
16 good long-term remedy. One is it didn't work in our
17 experience, frankly. The other is that it does actually
18 allow dispatching inefficiency. That is something that we
19 can afford and we ought to avoid. It results in
20 circumstances where you dispatch less efficient thermal
21 units before you dispatch more efficient thermal units and
22 it does this on a regular basis. That is not something that
23 we should want to perpetuate under our market designs in any
24 sort of degree, in my view.

25 The energy markets its important that you get

1 efficient dispatch and one of the advantages of these
2 markets should be that they do get efficient dispatch so you
3 get the most efficient resources running first and the least
4 expensive resources running later.

5 The next point I'd like to make is that I think
6 local reserve markets are an under-appreciated aspect of
7 market design. I think that's something that flows directly
8 out of our experience with push. What we really need in New
9 England are more local reserves. We're not paying for those
10 reserves. That's why we're not getting them. That's why
11 that's an important part of our market design and
12 development plan is to get locational reserve markets with
13 scarcity pricing probably in the demand curve. That would
14 go a long way towards resolving some of the revenue problems
15 that these resources have and I think it under-appreciated -
16 - part of it also is that it takes some of the pressure off
17 of the ICAP market and the locational ICAP market. People
18 are very concerned about very large ICAP prices. One of the
19 reasons that you have them is because you don't have this
20 locational reserve market and you're using locational ICAP
21 as proxy for these reserves. So you're paying everybody a
22 lot even if they're not really providing you with reserves.

23 If you can sort of disaggregate those products
24 and say, look, I'm willing to pay reserve resources a
25 certain amount it takes the pressure off the locational ICAP

1 market. It means you don't have to try to reward everybody
2 for providing a service they're not really providing to you.

3 My fourth point, I guess, would be that out of
4 market actions are a bad sign. This has been said before.
5 We are doing them in New England but they're a bad sign.
6 RFPs and RMRs should only be a last resort and should only
7 be in targeted instances. A good instance in New England,
8 it might be we have a couple of islands off the coast of
9 Massachusetts that are never going to have a competitive
10 market and essentially, there is generation and of course
11 the transmission system. You can imagine a case where that
12 would be an appropriate long-term solution. It would be an
13 RMR contract but, in general, they should be an integral
14 part of your long-term market design.

15 I guess the final two points would be the
16 lumpiness problem, in my view, is overstated. We've had
17 significant investment in both of our load pockets and we
18 still have problems. I think it is the isolated example
19 where there's one investment that solves the problem
20 completely. In reality, it's the incremental investments
21 that you don't get.

22 Finally, I'd just like to remind everybody, and I
23 think the ISO understands this, that in the long run you
24 can't avoid paying the costs for new entry. You have to
25 have a market design that allows that to encourage that new

1 entry and that's the unavoidable fact of all these markets
2 and we all ought to keep that in mind. Thank you.

3 MR. COLEMAN: Thanks Bob. Our last speaker on
4 this panel is Gunner Jorgansen from Select Energy.

5 MR. JORGANSEN: Good afternoon. I'm Gunner
6 Jorgansen appearing on behalf of the Northeast Utility
7 System. My remarks reflect end use experience in New
8 England and addresses, No. 1, the importance of additional
9 infrastructure in mitigating local market power and also
10 meeting reliability needs and two short-term and long-term
11 solutions.

12 Like PJM, the electrical load pockets of New
13 England are also focal points for the debate over-balancing
14 local market power, mitigation with the need to maintain
15 local reliability and generators economic reliability. The
16 key to success in mitigating possible local market power
17 issues is having market design elements that produce
18 efficient short- and long-term market signals to ensure
19 infrastructure. Peak and bonus must be laid out many years
20 in advance to provide clear, long-term market signals as
21 incentives for generation transmission and load response
22 enhancements.

23 New England's standard market design began March
24 1, 2003 and the resulting LMP price signals have been
25 successful; particularly, Connecticut's decision about

1 infrastructure. The Northeast utility system is built in
2 their submission infrastructure to assure greater
3 reliability and resource adequacy in southwestern
4 Connecticut, but they're not completed yet. Attempts to get
5 the market signal right in resource constrained areas of New
6 England have produced a series of successive interim
7 solutions as well as broadly different cost allocation
8 mechanisms. These changes create uncertainty. Some
9 Connecticut long-term requirements, not that they are
10 piecemeal, due to uncertainty over new market rules and
11 expect the high opinions by suppliers. Thus, efficient
12 long-term capacity procurement from generators is
13 jeopardized.

14 With this said, I commend the Commission for
15 recognizing the need to address resource adequacy, market
16 solutions in certain New England subregions. The New
17 England stakeholders process is now in its 11th hour
18 producing a mechanism that implements locational and
19 deliverability requirements in the ICAP and resource
20 adequacy markets from June 1, 2004, in response to
21 Commission directives.

22 As I speak, the New England ISO-ICAP problem is
23 for local areas prong to reliability of lack of power
24 issues. This phase-in period coincides with the expected
25 time it takes to complete certain transmission upgrades and

1 to begin the development of additional capacity after the
2 phase-in. The proposal creates an immediate locational
3 capacity obligation for a local load enterprise to phased in
4 pricing mechanisms for all the required resources in the
5 area.

6 Local peaking resources, in addition, are
7 guaranteed a common transitional payment in recognition of
8 the local reliability role during the phase-in period. This
9 is similar to ISO New England's RMR contractual rents accept
10 of transitional price. Not an individual negotiated price
11 is available to all eligible resources. All parties would
12 have the opportunity to view the units eligible for the
13 transitional price treatment and review the cost factors
14 making up the transitional price.

15 Planned resource additions are expected to occur
16 by the end of the multi-year phase-in. Then we envision
17 that a New York-styled ICAP demand curve is the long-term
18 pricing signal for this subregion. This solution is also
19 being actively debated within New England at the moment of
20 why is the phase-in necessary. New resources have various
21 deployment times. Time lines mostly require three or more
22 years, all depending on the resource technology and
23 magnitude and local sighting issues. Thus we see the need
24 to avoid and we did.

25 Imposition of long-term economic signals on

1 current consumers when the market and infrastructure
2 additions are incapable for an immediate response to the
3 signal. What happens in the Connecticut-specific demand
4 curve were implemented immediately without a phase-in
5 provision. Consumers would be exposed to 6 to \$700 million
6 annual of price signals from additional resources. This is
7 an unnecessary transfer of wealth. The phase-in arrangement
8 provides direct revenues for high as well as low capacity
9 units in combination with infrastructure investments. This
10 should provide the necessary market power mitigation by
11 creating stability in the marketplace. We see this as a
12 pragmatic balancing of difficult issues.

13 The proposal following the Commission's approval
14 would provide a well-defined set of pricing structures which
15 permits ISO New England to maintain its role as a market
16 referee and not become a market participant, would relieve
17 ISO New England from competently negotiating RMR contract
18 pricing terms under duress following by lengthy Commission
19 rate proceedings. This concludes my prepared remarks. I'm
20 available for questions.

21 MR. COLEMAN: Thanks.

22 MR. GRAMLICH: I had a question. First of all,
23 I'll make a quick comment. As you know, we always try to
24 get the balance of load and generation on these panels.
25 Sometimes we succeed. In this case, some of the load-

1 serving entities who buy and pay for our local market power
2 mitigation measures have representatives from other parts of
3 the company. We will have an open-mike opportunity.

4 I'll jump into the question. On the last panel a
5 few people criticized the option of loosening mitigation if
6 you find a case where price signals are not being sent where
7 they should be sent and I heard, Bob, you say that can
8 happen where sometimes you wind up with a result that you
9 don't have enough market power to get the price high enough,
10 which is not the problem people usually think of.

11 People on the last panel were saying actually the
12 problem is you end allowing market power to be exercised
13 where you don't need the price signal. I guess I'd like to
14 confirm with you that you can wind up with both problems,
15 then get others to comment. I think, Richard, you spoke
16 about the idea that mitigation should be loose or
17 nonexistent in load pocket areas, so if you could comment.

18 MR. ETHIER: That's an accurate summary. I'd
19 elaborate slightly by saying that one of the reasons the
20 price didn't reflect the cost of the generation is because
21 what we were really buying were reserves. In Connecticut
22 and in Boston, we often call on inflexible steam resources
23 to provide reserves for long stretches of the day because we
24 have insufficient quick-start capacity in those areas. So
25 while these particular resources, we have been benefitting

1 from relatively high-offer prices, there was no useful
2 market signal sent that a new entrant could respond to and
3 hope to receive by entering the market. So to the extent
4 that there were increased revenues to generators, it served
5 the need to keep the generator around, I suppose, but it
6 didn't serve also the important need of inducing new entry.
7 It was a combination of insufficient market power, if you
8 will, and also what we were buying wasn't really energy, it
9 was reserves.

10 MR. RAPP: I think my comment was that we
11 understood the need for mitigation in certain instances to
12 temper market power, but it will give you an opportunity, in
13 response to your question, to sort of address New York
14 specifically and where KeySpan thinks there should be some
15 modification to loosen up mitigation as it exist today.

16 First, with respect to the day-ahead market,
17 we're currently being mitigated on a 24-hour block basis.
18 KeySpan feels that if mitigation is appropriate, it's
19 probably only appropriate in certain hours or a certain hour
20 of the future day. That should be addressed more
21 specifically than having us mitigate it on a full 24-hour
22 period.

23 Secondly, my remarks were that there shouldn't be
24 mitigation as it reflected the real-time price. And because
25 there are real-time changes, such as changes in the gas

1 market, say, if that's our fuel of generation, they can
2 occur over the course of the day. The ISO really doesn't
3 have the ability to address those real-time changes and
4 effectively mitigate us to the extent that it isn't punitive
5 to us.

6 MR. CORNELI: Rob, if I might respond, also. The
7 push bidding experiment shows two things that seem like they
8 work in the opposite direction. One that is relaxing
9 mitigation doesn't seem to help very much and the other is
10 that, at least from a number of our perspectives, mitigation
11 still matters.

12 The real matter here, at least from NRG's
13 perspective, is that energy prices matter a lot. Energy
14 prices -- let's put it this way, what you can't recover in
15 terms of your fixed cost in the energy market you have to
16 recover some place else, whether it's reserve markets or
17 capacity markets. The more that can be recovered at
18 scarcity prices or high-energy prices at times when demand
19 is high the less need to come out of these other mechanisms.
20 Relaxing mitigation is one way to do that. I certainly
21 agree with David Patton's observation this morningning, that
22 that can work in two different ways, neither of which is
23 necessarily what anybody would want to have happen.

24 It seems that the critical issue here is figuring
25 out what is to get higher, prices at times when demand and

1 supply condition warrant that. There's obviously the
2 reserve shortage price and there is pricing of other system
3 actions that take place for and around reserve shortages to
4 keep them from happening and dropping the voltage. Asking
5 for a voluntary load, reductions, recalling extra capacity,
6 there's a whole bunch of steps like that and there's pricing
7 out of various different short-run marginal costs, the high
8 end of output of a thermal unit on a hot day and when
9 there's a higher risk of tube failure and being short in the
10 real-time market has a much higher short-run marginal cost
11 than the average fuel cost of that machine.

12 That could be reflected in bids. I think all the
13 ISO tariffs have provisions for that sort of thing to be
14 reflected. So I'm not sure it's used very much. It can be
15 reflected in reference prices as is done in New York. So
16 there's a variety of ways, both by relaxing mitigation but
17 probably more important by making sure that the systems in
18 marginal costs, which may be much higher than any
19 generator's fuel costs or actually setting energy prices.
20 Those are critical steps and I think the lesson of push
21 bidding is that, hey, there's not as much market power as
22 people thought, at least, in that load pocket and probably
23 others.

24 If you want to get higher energy prices, as the
25 Commission clearly did, you need to look some of these -- in

1 the Delmarva order you need to look at some of these other
2 measures making particularly sure that you're not using
3 mitigation to hold people to their short-run marginal costs
4 when it's something higher than that clearly is warranted.

5 MR. GRAMLICH: How do you balance that with the
6 financial and the investor representatives who discuss the
7 need for long-term contracts? Do you say what most of the
8 economists are saying, which is get the prices right. If
9 the prices aren't right -- if they're too low in a situation
10 where there's scarcity, then get them right and David Patton
11 and others have given some options to fix the market designs
12 to do that. Your theory seems to be if you get the prices
13 rights the loads for the entity must sign the long-term
14 contract. Do you think that's going to happen?

15 MR. CORNELI: I think that is the basic theory.
16 What we're seeing in the New York locational capacity market
17 is an interesting correlation, if not a causation, and
18 that's that we have the SES project that was talked about
19 and the LIPA RFP, both coming out for 10-year or long-term
20 purchases for capacity new development at the same time.
21 That LSEs are issuing these RFPs and facing a locational
22 capacity market. Energy prices, even when mitigated, can be
23 in the multiple hundreds of dollars and a capacity market
24 with a demand curve that holds capacity prices up so that
25 the expected cost stream to a buyer is high. I think what

1 you're seeing is likely to be those buyers seeing prices
2 going up above the cost of the contract and sellers who are
3 going down below the cost of the contract. Their getting
4 together and saying let's make a deal. I think that works.

5 MR. FALK: What I was going to say about that is
6 essentially the same thing. In a world in which prices are
7 held down, it shouldn't be surprising that no one has any
8 great interest in signing a long-term contract. They think
9 they can only lose on such a deal. And so it goes back to
10 what was said at the first panel, if the prices are right
11 and are truly reflecting these things, it would then be in
12 the load's interest and the mechanisms where they're allowed
13 by the state commissions or through the load's own self-
14 interest, I think will develop because they don't want to be
15 whipsawed any more than anybody else.

16 MR. WEMPLE: Rob, just from the perspective on
17 LSE, my retail affiliate, Con Ed Solutions, does have a lot
18 of load. On getting the price right is right for a couple
19 of reasons, it's not going to make any retail LSE go out and
20 hedge longer term than its retail sales are, to do so would
21 be a speculative position. So for a couple of reasons it's
22 important to get the price signals right. It might make
23 regulating utilities a bit long-term. Regulatory compacts
24 do something different, but a retail LSE can't afford to go
25 out and buy a five-year contract for supply if its retail

1 sales are only a year and a half in duration.

2 The reason it's important to get the prices right
3 is because the uplift, which is an unhedgeable cost, is
4 financial suicide for marketers. For us to guess at a price
5 and convey it to the end use customers, we have to pad
6 uncontrollable prices a lot because you can't control them
7 by definition. You don't want to be on the wrong side of
8 the equation. It also dampens out whatever demand response
9 you were hoping to get for the limited customers who are
10 willing to switch fuels or do something different in
11 reaction to the right price. If you're not generating that
12 right price in the first place, you're not going to get the
13 demand response you want.

14 MR. REEDER: I wanted to comment more about --
15 there were some comments that peakers are something you
16 can't recover anything more than their valuable cost. I
17 think it was pretty clear but that's true if you have no
18 decent rules for scarcity anywhere. But if you have decent
19 scarcity prices, they definitely can.

20 In New York we have demand side that bids, 200,
21 300, 400, 500, any of those can be on the margin well above
22 a peaker. If you don't have enough of that, the price could
23 go to a thousand if you're short of reserves. So let the
24 scarcity itself, if it's truly occurring without
25 withholding, drive the prices to the 200, 400, 500 or a

1 thousand and the peakers do fine.

2 So in some of the situations it may just be the
3 lack of enough scarcity, but that raises the locational ICAP
4 concerns because enough scarcity to produce compensatory
5 revenue streams for a peaker without any ICAP may be way
6 more scarcity than society in New York City and places like
7 that want. So the ICAP market, in essence, is saying we
8 don't want to push scarcity that far. So it has enough for
9 days when we're really short to be compensatory. We're
10 going to compromise by giving extra revenue streams for ICAP
11 so that scarcity doesn't have to do it. But please, peakers
12 can get revenues well above their running costs by bidding
13 their running cost every hour. The studies David Patton has
14 shown show that. They're not fully compensatory because we
15 have excess in a lot of places.

16 It's certainly not proof if generators are
17 allowed to exercise market power and they cannot raise
18 prices to their long-run average costs. That's not proof
19 that they don't have market power. Many markets get gauged.
20 They get surplus and the natural competitive price. You get
21 a thousand players, each with a 10th of a percent of
22 surplus, is pretty low. The natural price, if you only have
23 six players with surplus, may be significantly higher than
24 that but not all the way up to the long-run average cost.
25 So market power can pull you above the competitive level but

1 still keep you below that sort of long-run average cost.

2 Just one other thing, I think there was a comment
3 that there hasn't been much mitigation, much market power.
4 Well, New York City has had its mitigation measures triggered
5 just constantly. So the fact that you haven't had really
6 higher prices isn't a sign that you haven't had market
7 power. It is a sign you haven't had market power, but it's
8 not a sign that you should feel free that if you lift all
9 the mitigation measures you would continue to not have
10 market power. The reason you don't have the market power is
11 because the mitigation is kicking in a lot.

12 MR. SINGH: Mark, you mentioned earlier that when
13 set the demand curve for reserves you should take into
14 account the revenues that you get from energy and from the
15 ancillary services markets. So we heard this morning of
16 scarcity pricing for energy and scarcity pricing for
17 reserves and, obviously, the demand curves. It would seem
18 then that we have some digress of freedom. We could pick
19 one really high and then the other one would be lower
20 because you have a very high cap in the energy in the way
21 you set up the administered scarcity pricing there.

22 Your demand curve, presumably, for ICAP would
23 come out differently based on what you said earlier. Are
24 there limits or bounds on how much we can tweak this in the
25 extreme? You could certainly get rid of ICAP if you have a

1 very high bound on the energy side. Do you have any
2 thoughts on that?

3 MR. REEDER: You're exactly right. A real world
4 example, when we were doing an analyze of what the demand
5 curve height should be for installed capacity, we had to
6 make an adjustment because we used historical data, which
7 produced the amount of revenues peakers get from the
8 ancillary services data. But we noted, wait a minute, we
9 just load for scarcity pricing rules that aren't in last
10 year's data. They will be in next year's data. We need to
11 adjust upward what the peakers will get from the energy
12 market when the new scarcity rules go in and that let's you
13 adjust downward as you suggested.

14 The demand curve, in the limit, if you get enough
15 demand response, that is your way of responding to load
16 growth for the next 20 years, let's say, real-time pricing,
17 things like that and that's what you get instead of peakers
18 or instead of generation. Then instead of peakers on the
19 marginal lot at \$100, you have demand response on the
20 marginal lot at \$250. You can get a world where the energy
21 market is fully compensatory to hard wire generators called
22 peakers without having any involuntary blackouts. The one
23 day in 10 years is fine. That's an involuntary proposal.
24 When you have voluntary people cutting back, the price
25 clearing at 200, 300, 400, everyone who wants power gets it.

1 The peakers make plenty of money. The ICAP market can go
2 away. That might be a dream but that's a long-term view
3 that we could try to strive for and that's how I think it
4 could work.

5 MR. FALK: I just wanted to say one quick thing
6 about what Mark said. I don't want to not characterize New
7 York City as a load pocket. If we were going to start
8 defining our type of load pockets, I think New York City
9 would be one. But you cannot draw the conclusion just
10 because the market mitigation measures have been used a lot
11 that the market mitigation measures have necessarily been
12 effective since, after all, the bids people make they make
13 with the knowledge that they're about to be mitigated. So
14 we don't know what the regime would be like with a different
15 set of mitigation measures.

16 Now I'm not saying that New York should be
17 immediately set loose, but I think that there's a real
18 threat here that I put on a market mitigation measure and
19 you say, see, look, it worked because I mitigated all these
20 bids around. But of course, you bid differently in a world
21 where you know you have a backstop that someone will change
22 your bid down to your marginal cost if your bid turns out to
23 be too high. So you have to take into account what people's
24 incentives are in the bidding. They will always be
25 conditioned on whatever the mitigation happens to be. I

1 don't think that necessarily goes to the New York City
2 example, but I think it's an important point to bring out in
3 general.

4 MR. ETHIER: Harry, you mentioned it seems like
5 we have some degrees of freedom and I think you're exactly
6 right. But I think we need to recognize that there are some
7 real implications of how exercising those degrees of
8 freedom, what that will have on the resource mix. The two
9 obvious ones are the thousand dollar offer cap. If you were
10 to lower that substantially, you may reduce the amount of
11 demand response. You may get fewer megawatts for emergency
12 ranges of units, which, for example, in New England helped
13 us out a couple of weeks ago. So you want to be careful
14 about precluding resources from participating in the market.

15 And the other one that nobody's even had to
16 grapple with, with any luck New England will have to soon,
17 is if you look at the demand curve reserves, depending on
18 how you shape that, you can dramatically change the
19 incentives for what kind of resources you're bringing into
20 the pool.

21 In New England it's pretty clear at this point we
22 need quick-start capability. We're on record with that.
23 But in the long run, it's unclear to me how you make clear
24 lines about how much of each resource you want. That's a
25 problem that we'll have to deal with down the road, but I

1 just want you to be aware, you're right, you can mix and
2 match, but you're going to get downstream implications for
3 the underlying physical facilities you get in your
4 marketplace.

5 MR. O'NEILL: Some of you made reference to
6 calculations about not earning your capital costs. In a
7 market that's got excess capacity, wouldn't you expect that
8 to be the case and in a market that was short, wouldn't you
9 expect that number to be higher and what are the
10 implications? If you want us to do something now when the
11 market is in excess capacity, shouldn't we do something when
12 the market is growing short?

13 MR. FALK: There's no question that in a glut you
14 won't earn your capacity costs back. That's simple
15 economics. The flip side of that is, okay, then let me
16 mothball the unit for a year. Let me take it out. I'm not
17 going to make even my fixed O&M on the unit. I want to be
18 able to leave the market. If you're stuck in the market to
19 simply bear those costs, that sounds like a taking to me.

20 MR. O'NEILL: That's a fair point but that wasn't
21 the question I asked. What lesson should we take from the
22 fact that in a glutted market you're not earning a return
23 until, let's say, a standard cost of service calculation.

24 MR. CORNELI: Let me take a shot at that and see
25 if this gets to your question, Dick? There's a glut

1 globally but there's not always a glut locally. For
2 example, there's the constrained areas of NEPOOL that have
3 actual shortages of the needed level.

4 MR. O'NEILL: I was being generic. I wasn't
5 trying to hone in on anything specific, but you raised the
6 point about not earning in a glutted market enough to cover
7 a cost of service calculation. If we're to act on that when
8 you're not earning enough, there's an implication that we
9 should be acting on that when you're earning too much. I'm
10 not sure either one of those is a good strategy.

11 MR. CORNELI: If you took from my presentation
12 that you think we ought to be paid the clear cost of
13 service.

14 MR. O'NEILL: I didn't. It was others.

15 MR. CORNELI: I think the way that ought to work
16 is that if there's a shortage you should be earning more
17 than your full cost of service and if there's a glut, you
18 should be earning less.

19 O'NEILL: There's no real full cost of service
20 calculation.

21 MR. CORNELI: Let's put it this way, you should
22 be earning enough.

23 MR. O'NEILL: Over the long run, you should be
24 earning enough to earn the return on your investment, but
25 the short day-to-day calculations or year-to-year

1 calculations can give a very misleading signal, so you take
2 them over a very short period of time --

3 MR. CORNELI: I think on a shortage situation the
4 misleading thing should be that you're making more money
5 than you'd like to later rather than you're making less
6 money than you'd like to later.

7 MR. O'NEILL: In a shortage situation, yes, but
8 the problem is if you keep pointing out to us that you're
9 not making enough money based on this calculation and we
10 should do something about it, the implication is that we
11 should also do something about it when you're earning more
12 than that number.

13 MR. WEMPLE: Richard, if you look at the
14 historical levels, say, from '99 through '03, we've been
15 under recovering and the next two years we expect to also be
16 there. One would expect a comparable period of over
17 recovery. I know it hasn't been the Commission's policy to
18 preclude over recovery, but the political reality is when
19 the prices jump up there tends to be a bias towards
20 additional mitigation, additional price caps. I do not have
21 confidence that the political environment will allow people
22 to over recovery for a sufficiently long period of time
23 during scarce situations to offset the under recoveries
24 we've had for the last four years.

25 MR. O'NEILL: What's your solution?

1 MR. WEMPLE: Market reforms to have more rational
2 outcomes and I think the capacity market behavior going to
3 zero in New England when units are needed suggests --

4 MR. O'NEILL: I thought we just agreed that the
5 rational outcome when there's excess capacity is you don't
6 make that number?

7 MR. WEMPLE: But to fall as far down -- nobody's
8 suggesting in a surplus market everybody should get their
9 return, but we've had such a cycle and gone so far from
10 where new entrants need to be for anybody to have confidence
11 to put more merchant money at risk. We have to have an
12 expectation that you'll have enough years above and enough
13 years below, and the last four years have been so far below
14 and the next two years are also going to be below. I've got
15 six years of history that says the market's not going to
16 compensate a peaker. I have no confidence we're going to
17 get six years of over collection.

18 MR. O'NEILL: But the lesson we should take away
19 is that we should get the market design correct, make sure
20 there's appropriate scarcity pricing, but not to try to
21 compensate you over or under that number.

22 MR. WEMPLE: I agree.

23 MR. FALK: I think we all agree on that.

24 MR. PERLMAN: Can I ask a question about that,
25 gentlemen? From my understanding from what you were saying

1 is that you were adverse to any kind of mitigation.

2 MR. FALK: You have to read the long paper not
3 the short paper, but, no, that's not right. I think my
4 paper comes from the observation that we seem to be so
5 afraid of market power that we're probably over mitigating
6 but that doesn't mean, I don't believe, that there are
7 certainly all kinds of situations in which mitigation is
8 warranted. The most classic example, if you think to the
9 auction proposal, the auction proposal which we want to get
10 enough resources into bid in one of these situations and it
11 might take three to four years to bid mitigation for that
12 entire period up until that new resource could come into
13 line. There's no reason for the incumbent generators to
14 simply earn monopoly rents for the period that it would take
15 to build their competition. There's no obvious productive
16 efficiency or any other sort of result from that. It's not
17 that I'm opposed to mitigation. It's that you have to think
18 about why you're mitigating, who exactly you're helping and
19 who exactly you're hurting and what you're doing about long-
20 run productive efficiency.

21 MR. PERLMAN: I understand. But what I think we
22 talked about this morningning was the structure where you
23 have scarcity pricing with the administratively set
24 component for the scarcity and operating reserve component
25 but with relatively robust mitigation in the energy market

1 sort of when those things were not impacting prices, so you
2 would end up with sort of with a mitigation structuring
3 today but with additional opportunities in times of scarcity
4 or however we define them. Is that something you'd be
5 comfortable with?

6 MR. FALK: I agree with that but my takeaway with
7 that is that once the prices is right, and I think Bill said
8 that mitigation problems present themselves, it's actually
9 now a much smaller set of units. It's a much easier to
10 define set of problems and you take them on one at a time.

11 MR. TIGER: A follow-up question on, perhaps, we
12 have this question about the mitigation in New York and it's
13 mitigated 50 percent of the time in the day-ahead market and
14 presumably we have these debates internally about whether
15 the market signals are being sent in situations where there
16 is that kind of mitigation. Presumably, there are projects
17 on the board. You mentioned two of them, specifically, New
18 York load pocket. Maybe you can talk a little bit, both of
19 you, in terms of capital looking at mitigated prices and how
20 you compare the PPAs that are underlying projects versus the
21 market prices that you receive that may have an
22 administratively determined component and a market
23 component.

24 MR. ANDERSON: Jonathan, I might take a first
25 crack at that. You have a broader perspective as an advisor

1 on these, but here are two topics and these is meant to be
2 somewhat responsive to your point, Mr. Gramlich about what
3 do we mean when we're talking about contracts. I hear some
4 discussion about there needs to be a price signal that will
5 tell capital you can get your return if you come when you
6 get to the point that you need new capital to come in and
7 build peaking units. My comment about me providing long-
8 term capital for power infrastructure is a little separate
9 topic as one of needing a signal to get capital in and the
10 second separate topic is what kind of capital are you
11 attracting? Do you have a volatile system where someone
12 with a 25 percent return requirement says, okay, I've now
13 got a rate design that will allow me to deploy my equity
14 capital in here and take a bet on building a peaking unit?
15 Or do you have something with more predictability and a
16 long-term contract that the debt investor can rely on and
17 that has to be backed up by the load-serving entity seeing
18 his ability to pass that through? If you do, you've now
19 unlocked 7 percent return capital, to use an example. So
20 you're blended cost of capital and return that the ultimate
21 user has to pay it is now 13 percent instead of 25 percent.
22 So I hope that puts a little bit in context my narrower
23 comment about contracts versus the broader discussion of a
24 level of returns has to be high enough to attract capital.

25 MR. O'NEILL: It sounds like a great deal for the

1 buyer.

2 MR. ANDERSON: That's right. That's the power of
3 unlocking some debt capacity in this market as opposed to
4 having it be so volatile that, while theoretically complete,
5 it's an equity only market that's going to be a more
6 expensive proposition for the ultimate consumer.

7 MR. O'NEILL: And I guess the culinary is it's
8 going to be more expensive if you want to live in the spot
9 market than it is if you basically sign long-term contracts
10 that follow the rest of the investment?

11 MR. ANDERSON: That's right. In the long-term
12 contract for your full requirements you'll never get it
13 right, so you try to figure out that right mix of how much
14 you can make a long-term commitment for and how much you
15 need to leave open because you know the future will always
16 be different from any one projection, but we agree on the
17 basic premises.

18 MR. BALIFF: I think the nature of what you're
19 hearing from us is that your return market is the signal,
20 okay? Unfortunately, I can't comment on the angel's dancing
21 on the head of the pin. However, I can tell you that that
22 market, to get it right is important because it is going to
23 be the basis of these contracts which, again, are the
24 necessary but not sufficient condition. That being said,
25 and that's by the way, is the 7 percent money. You're

1 looking at the 7 percent money. We're having access to the
2 25 percent money. By the way, that doesn't mean that this
3 money is smarter than this money. To say that there have
4 been dumb investments in this sector is an insult to dumb
5 investments.

6 (Laughter.)

7 MR. BALIFF: But the idea is if you want to
8 create the solutions that are long-term solutions not short-
9 term solutions, you need to be able to have the right
10 market. If it's a dumb investment, just like Bill said, you
11 lose the money. So what, you know, that's the risk that you
12 take. The issue that we're getting into from our side is
13 the risk measures almost compound each other if the investor
14 has to take construction risks combined with commodity risk
15 combined with regulatory risks. This is when you actually
16 start to see the market shutoff and you don't get
17 investment. There's a mix with the short-term and long-term
18 investors certainly who come into this market.

19 Right now we're on the cusp primarily because we
20 have so much liquidity that it might actually be masking
21 some of the problems that would be inherent, i.e., a
22 shutdown of the marketplace. Right now you don't have that.
23 I can tell you, you also don't want to have very hot money.
24 We're talking about the left side of the balance sheet the
25 way I think, the asset side. You want to have -- that's

1 very volatile given the nature of our market. Do you want
2 the right side of that balance sheet also to be hot money
3 coming in and out? I don't think so. That's why we need to
4 have some of these risk mitigation measures.

5 MR. PERLMAN: Can you describe what you mean by
6 "regulatory risk" and how we can act to reduce that risk?

7 (Laughter.)

8 MR. BALIFF: I think the example of probably the
9 regulatory risk, for lack of a better word, that freaks out
10 the investors the most are the reg out structures that you
11 saw in PPA contracts. And again, those were mostly -- they
12 can be state, but it's less (inaudible) based, okay? So if
13 you have a long-term, let's say, five year contract or we
14 have this 10-year contract with Con Ed for the SES plant --
15 I can tell you there are none of the reg outs that you saw
16 in the California contracts.

17 The investors are kind of fool me once kind of
18 investors. So don't think you can have that type of reg
19 out, but they're also concerned with rapid significant
20 market structure changes. Again, fool me once. They're not
21 going to be basing their cash flows on any type of rate
22 caps. I'm sorry, they'll base some of their caps, but
23 nobody going to think you can get greater than a thousand
24 dollars. That's for the equity. That's not for the debt.
25 The debt is really going to placing in their own performers

1 and their calculations a certain amount of what they
2 consider as reasonableness for the markets that are allowed,
3 and if there are rapid changes, that's the regulatory risk
4 that I'm talking about.

5 MR. COLEMAN: Now that we're getting ready to go
6 to break, to take a couple of minutes, as we said at the
7 outset, if there's anyone from the audience from the load
8 side who would like to make a comment we have a mike right
9 here. I would just ask that you'd give your name and your
10 affiliation for the court reporter so it can be transcribed.

11 MR. SASSON: My name is Myer Sasson from Con
12 Edison, the regulated company for New York City. I welcome
13 very much, Michael, your idea of the LSE viewpoint. There
14 are lots of ideas going through my mind from what happened
15 this morning, which I think was very, very good.

16 I'd like just to say that the transmission owners
17 in New York had a tight pool for about 25 years before the
18 New York ISO was created. I was part of the team that
19 formed and proposed the New York ISO to the Commission to
20 emulate the New York ISO 25 years of experience all the way
21 from mandatory rules to liability rules to capacity markets,
22 locational capacity markets and we have locational reserves.
23 We had them before. It was not a deregulated market but we
24 had all of those because they were all needed to keep the
25 lights on. That was the bottom line. I think that was

1 emulated from the New York ISO.

2 Right after the New York ISO was formed and we
3 started operating we did have to fix many flaws in market
4 design. We did not have the sophisticated mitigation
5 measures that David Patton put in that addressed the real
6 situations, especially in New York City. New York City has
7 load pockets. As a whole, it's a load pocket but inside New
8 York City there's many, many subload pockets; yet, it works
9 well.

10 If you look at prices in New York City in the
11 past month where we've had high gas prices, we've had very
12 high prices in New York City. The prices in New York City
13 do reflect what -- it's been the highest price in the state.
14 That is the right mix of prices that we should have because
15 New York City is the most congested portion of the state.
16 Where is generation? This morning it was very clearly
17 stated. Where is generation on site in New York City where
18 people are thinking they should be building transmission
19 into New York City? I think we have a market that has the
20 right balance of mitigation, scarcity pricing, locational
21 capacity, locational reserves that is providing the right
22 signals for generation and transmission to want to build.

23 The last point I wanted to make, a couple of
24 quick points is, and I think David and somebody else also
25 said something about this this morning, you don't

1 necessarily relieve a load pocket by building transmission.
2 That may not be the right thing to do. If the market wants
3 to do that, that's fine. From a merchant point of view --
4 but New York City is reliable with it's load pockets.
5 Remember, it was designed that way. When the vertical
6 utility had existed, it designed New York City with all its
7 load pockets as the most reliable utility in the whole world
8 and it still is.

9 The idea that load pockets mean unreliable
10 systems just doesn't add up. We operate to a second
11 contingency in New York City, a higher availability measure
12 than anywhere else and we are reliable with our load
13 pockets. So if, from a merchant point of view, there's a
14 thrust to build into New York City, that would be great.
15 That's fine. But it's not necessary from a reliability. We
16 need to keep that balance in mind.

17 The last comment, not to abuse what you have
18 offered me is -- it's an open mike.

19 (Laughter.)

20 MR. SASSON: Is that we had an RMR problem in New
21 York City because of all these load pockets and subload
22 pockets it was very difficult for all of the market design
23 to bring in all of the reliability requirements into the
24 market. So very frequently our operators in New York City
25 needed to say we need to increase generation, take it out of

1 the market and we'll call it out of merit. It's an RMR for
2 a few hours. Yet, we work hard with the New York ISO and
3 came up with changes in the market design that were able to
4 bring the RMR into the market design so that now the
5 selection of the RMR unit, and there may be more than one
6 unit, that must run at a higher level in a given load pocket
7 to resolve the reliability problem is no longer dictated
8 manually. It is within the market rules. It effects prices
9 and, yes, there is mitigation and it is subject to
10 mitigation. With mitigation, we have had high prices in New
11 York City and I think that is the right mix. Thank you very
12 much for giving me this opportunity.

13 MR. KATHAM: Can I ask a question that has to do
14 with -- we've been talking in the first panel and this panel
15 about LSEs and signing long-term contracts. Could you speak
16 to Con Ed's decisionmaking and why it decided to go and sign
17 long-term contracts?

18 MR. SASSON: I would rather not address the
19 question right now. There's a reason for it and it is that
20 my involvement has not been close enough to that decision to
21 be able to do merit to your question. It's a very serious
22 question. We would, in written comments, reply to it. We
23 were advocating the need that in capacity markets we do need
24 more long-range capacity structures than we have today, and
25 the reason for that was we were convinced that the financial

1 markets needed more long-ranged signals, steady signals than
2 a six month-to-six month capacity market that we have today.
3 That is one thing that we're working on. The very, very
4 specific issue you're mentioning we'll address.

5 MR. COLEMAN: Along those lines, Jonathan, you
6 said that Conjunction Project -- project as well.

7 MR. BALIFF: Auction is following the FERC rules
8 for an open season. That auction will commence at the end
9 of February. We will be going out with contracts. What we
10 are seeking, though, is actually not one player, even if Con
11 Ed came in -- maybe we'd make an exception.

12 (Laughter.)

13 MR. BALIFF: The idea is we'd like to have
14 diversity of contracts very similar to what you see in the
15 gas pipelines so that you don't have -- it'll be easier to
16 finance in the marketplace because you'll have diversity,
17 but we have to follow the open auction season.

18 MR. PERLMAN: I'm sorry. Thank you for point
19 that out. Do you have a duration of contract that you're
20 going to need in response to that process to get financing?

21 MR. BALIFF: We are looking at 10-year contracts
22 as the heart of the envelope. It is an open market process
23 that the FERC designates for good reason, and really what
24 we're going to do is follow what the market tells us it can
25 do. And obviously we have to cross-check to make sure it's

1 financiable, but it's an interplay between the term of the
2 contract and the price of the contract. And in these
3 financing markets, the good news is we can accept some
4 things that we probably couldn't accept four or five years
5 ago because of the low cost nature of the capital markets.

6 MR. O'NEILL: Would you do anything differently
7 if we didn't have open season requirements?

8 MR. BALIFF: Yes, we would.

9 (Laughter.)

10 MR. BALIFF: I think the nature of what we'd want
11 to do in transmission is to try and make it look more like
12 gas pipeline and power gas pipeline.

13 MR. O'NEILL: They have open seasons.

14 MR. BALIFF: But it's a different type of open
15 season. I'll put it this way, what would I do differently?
16 I'd like to take a hiatus for 5 or 10 years, have a couple
17 of more open seasons happen, then come back and start
18 financing. It's a very difficult process now because the
19 open season on gas pipelines is such a tried and true
20 measure. The nature of that market in getting the open
21 seasons more toward negotiated contracts is just much
22 quicker. There's less uncertainty. An electric
23 transmission, because it's all so complicated, though,
24 because of the nature of our contracts cannot be physical
25 contracts. That's a huge difference. The physical contract

1 for a gas pipeline, which is under an open season, means the
2 offtaker has physical capacity. In electric transmission
3 lines you do not get that because of the nature of the New
4 York ISO says that you cannot have that. They must control
5 the line.

6 MR. O'NEILL: Even in the D.C. line?

7 MR. O'NEILL: Even in a D.C. line.

8 MR. COLEMAN: Our time is up here.

9 MR. O'NEILL: It would be nice if we could
10 understand the differences between the gas and electric open
11 season that you would like to see.

12 MR. COLEMAN: I want to thank the panel. I have
13 3:14 by the clock on the wall. We're going to take 10-
14 minute break and get set up for the last panel. Then we're
15 going to start promptly at 3:24. Thanks.

16 (Recess.)

17 MR. COLEMAN: Okay, folks, we're going to get
18 started with the last panel here. Out of courtesy, if you
19 could sit down or move your conversation outside.

20 We're going to get started here with our last
21 panel this afternoon, as we have in the morning, a more
22 board overview of some of the RMR issues. We just finished
23 up with a panel dealing with Northeast issues. This last
24 panel is going to give us some insights into some of the
25 local market power issues in other regions of the country

1 which we haven't addressed yet. So we'll have a panel that
2 covers a much broader geographic spectrum. We're also
3 starting off with a financial perspective on this.

4 The first panelist here is Howard Newman, Vice
5 Chairman of Warburg Pincus. We're delighted to have you
6 with us, Howard, for a comments. Thank you. You have five
7 minutes to impart all your wisdom upon us that you'd like
8 to.

9 MR. NEWMAN: Thank you. I don't have a lot of
10 wisdom to impart to the technical part of this panel. I'm
11 delighted to be here today. Warburg Pincus is a specialized
12 private equity firm with significant experience in the power
13 business. We were financiers of a company called the
14 Jamikowski Company in the mid-80s which developed a lot of
15 power plants in the New England market around the Iroquois
16 pipeline. We got out of the generation business in the mid-
17 90s and entered it again in the late-90s with an investment
18 in a company called Competitive Power Ventures and two other
19 companies, one of which was called Nuclear Generation and
20 one of which was called Insight.

21 We have some experience in being on the supply
22 side part of the energy markets, and I think my comments
23 here today would reflect how we view the issues from the
24 supply side, and to some extent how some of the issues in
25 the must-run issues relate to that. From the perspective of

1 a supplier of capital, what's most important to us is that
2 we go in a system where the rules are well-defined, clear
3 and stable. They provide adequate opportunity to earn a
4 return on and of capital. That's the long and the short
5 perspective of what it means to be a provider of equity
6 here.

7 In making those assessments, you balance the
8 opportunities and risks against the opportunities in other
9 investments and we can look at this in a competitive sense,
10 in a market sense where the market is the market for our
11 capital. To put that in perspective, Warburg Pincus is a
12 private equity firm. It currently has investments in
13 private and public companies worth around \$10 billion and
14 has around \$5 billion available for new investment as we
15 speak, 60 percent of which is dedicated to the U.S.

16 We are aggressively and actively looking for ways
17 to get involved in the generation business, and to date,
18 have been unable to discover the opportunities which works.
19 As we look at the generation business, there are two parts
20 to it from our perspective. One is the energy margin, which
21 I think is the part of the business which we're very
22 comfortable with.

23 The part of the business which we're not
24 comfortable with is how we see what people refer to as
25 "capacity revenues" or the return on excess of the energy

1 margin. And as we've looked at the market structures which
2 people come up with, issues about whether you should rely on
3 price spikes for 1 percent of the time or whether you can
4 rely on an ICAP market or things like that. Those are the
5 issues that are most important to us. What we need is some
6 clarity and some permanence on how those mechanisms will
7 provide revenues adequate to support the capital which we
8 provide. That's the perspective I bring to this.

9 I think I will do something most speakers won't
10 do, is cede the rest of my five minutes to somebody who's
11 got some more technical comments.

12 MR. COLEMAN: I appreciate you ceding your time
13 to us, Howard. Our next speaker is Danielle Jaussaud,
14 Director of Economic Analysis and the Market Oversight
15 Division of the Texas Public Utility Commission. We're very
16 pleased to have you here to give us some observations about
17 what has happening in the great state of Texas.

18 MS. JAUSSAUD: Thank you. My name is Danielle
19 Jaussaud. As you said, I'm with the Marketing Oversight
20 Division of the Public Utility Commission from Texas. I'm
21 going to talk about the experience we have had in the ERCOT
22 market with load pockets and generation pockets.

23 The ERCOT market is a zonal system. We have five
24 zones and five commercially-significant constraints. Inter-
25 zonal congestion is resolved through redispatch and through

1 zonal bond and the costs are directly assigned. Inter-zonal
2 congestion costs are hedged TCR auction by ERCOT. Internal
3 congestion is solved through redispatch. In this case, the
4 costs are restricted to loads. It's applicable to all
5 loads.

6 Local congestion costs in ERCOT have been very
7 high between July 31st of 2001, when the market opened, and
8 June 2003. Local congestion costs amounted to \$550 million.
9 Of these, about \$60 million were for out-balancing energy
10 and about \$50 million were for down balancing energy to
11 solve local congestion problems and to solve those problems
12 when a competitive solution existed in that local area.

13 In June 2003 the total balancing energy costs
14 resulting in local congestion was \$58.8 million, which was
15 more than half the total amount since the market opened in
16 July of 2001. So we run into a problem because that the
17 method that we were using for solving local congestion was
18 faulty. I'm going to explain a little bit why it resulted
19 in this problem.

20 Under this method for solving local congestion,
21 bidders submit a resource-specific opening bid if a market
22 solution does not exist ERCOT deploys energy from needed
23 resources out of merit. Selection of the unit to be
24 deployed is based on the unit's chief factor times the
25 premium bid absent the market solution compensation for out-

1 of-merit is based on generic costs plus a percentage. The
2 percentage has been 10 percent.

3 Now a market solution is defined as three
4 unaffiliated resources that someone bids to ERCOT and than
5 solve a circumstance of local congestion and no one bidder
6 is essential to solving the congestion. If a market
7 solution exists to solve local congestion, the resource
8 selected is paid according to the bid premium that is
9 submitted. Some resources do not want to be deployed. For
10 example, many combined cycle units do not want to be
11 deployed. They do not want to decremented. For example,
12 cogeneration base-load units load nuclear and so on.
13 Resources were at some point instructed by ERCOT that if
14 they did not want to be deployed they should submit a
15 premium bid of a thousand dollars, plus a thousand dollars
16 if it was incremental energy minus a thousand dollars for
17 decremental energy. That would indicate to ERCOT that they
18 should not be deployed except as a last resort. That
19 approach turned out to be ineffective. It was ineffective
20 because bidders did not know when there was going to be a
21 market solution and they didn't know when to bid
22 competitively.

23 There was no incentive to bid competitively and
24 most bidder did at cap level to indicate load deployment and
25 that was also due, in part, to faulty deployment mechanisms

1 of some plants like the combined cycle plant. The market
2 solutions existed in less than 5 percent of the cases. This
3 is what we found. The approach was ineffective because no
4 disincentive existed to discourage generators from building
5 new generators and there was no incentive to build where
6 generation was needed.

7 In June 2003 what happened then was that a market
8 solution was created when a new generator built in a
9 constrained area, which happened to be a generator's pocket.
10 This resulted in this high cost of almost \$60 million to the
11 market in just one month. Immediately following that,
12 ERCOT's stakeholders committee voted to suspend the market
13 solution so that after that the competition was based on
14 generated costs only, even if there was a market solution.
15 A taskforce was created to explore alternative payment
16 options and another taskforce was created to look into
17 possible infrastructural improvements to relieve the severe
18 congestion that existed in that area.

19 The issues that the new solution needed to deal
20 with is that we needed to find a way to provide incentives
21 to bid competitively where our market solution existed or
22 exist. We needed to attract investments where new
23 generation is needed. We needed compensation that is
24 attractive but not so attractive as to create
25 inefficiencies, and we an experience with that previously,

1 where compensation for RMR was so attractive that a unit
2 seems to prefer being an RMR unit rather than play the
3 market and it was an inefficiency that was created. We
4 needed compensation that would assure efficient deployment.
5 In other words, we didn't want compensation that would lead
6 to the deployment of inefficient units before efficient
7 units were deployed. We needed to recognize that resources
8 cannot move easily nuclear, hydro, cogen, et cetera.

9 Finally, we needed to have a solution that would
10 have a moderate price impact. I'm pass my time and I can
11 stop here and maybe pick up with questions later on or in
12 the discussion.

13 MR. COLEMAN: Thank you, Danielle. Actually, I
14 see our next speaker is sitting between Texas and
15 California. And I think in terms of having a person to deal
16 with those markets, he's probably the best person we could
17 have here. John Meyer from Reliant Resources. Thanks for
18 showing up, John.

19 MR. MEYER: I want to thank the Commission for
20 inviting me to speak today on local market power mitigation.
21 First, just to kind of give you a taste of the issues that
22 Reliant's addressing, we operate in essentially all the ISO
23 markets except New England currently. We have roughly 5000
24 megawatts of supply in PJM, 3000 in MISO, 3000 in New York,
25 about 3000 in the Southeast, mainly, in Florida, 1000 in

1 Texas and 4000 roughly in California and southern Nevada.
2 We also have about 13,000 megawatts of peak load to serve in
3 ERCOT and several hundred megawatts outside of ERCOT in
4 various markets as a retail provider.

5 Having said that, I'd like to kind of get to the
6 crux of the problem. I kind of feel, speaking last,
7 particularly after the last two panels, like a father who'd
8 handed his son his fishing rod and reel. His son has thrown
9 the line out in the water and it's all tangled and he hands
10 it back to you and he says, will you fix it. e're going to
11 try to reach a perspective a little bit on this, but we've
12 had a lot of different comments today to deal with.

13 First of all, I think we'll generally agree that
14 this is not an easy problem to solve. No one has really
15 solved it yet either. We could probably also agree there's
16 not going to be a perfect solution or a "correct" solution
17 to the problem. There's going to be a solution we can come
18 up with. We'd also probably agree that we need to protect
19 the customers by preventing an uncapped or unheeded exercise
20 of local market power. However, one speaker did set this
21 right. We need to define market power correctly. That's
22 the ability to change price different from a competitive
23 level for a significant period of time, and I guess we could
24 argue about what each of those components means but not
25 today. I hope we can agree to some general principles and

1 that's kind of the way Reliant has approached this, to lay
2 out principles that may be needed.

3 We've come up with three basic things. Many of
4 them have already been talked about today, but we hope that
5 we can develop objective standards that define when
6 mitigation is required in a local sense. I guess, first, we
7 have to ask ourselves the question whether this is a
8 temporary local market power problem. In other words, the
9 line is out, the generator tripped off line, different
10 loading pattern today, or is this chronic. In other words,
11 is it predictable and it occurs quite a bit of the time,
12 hundreds of thousands of hours during the year? Then, as we
13 look at do we need to mitigate this congestion occurring,
14 and I think this is something most ISOs worry about, if
15 there's no congestion, obviously, why mitigate?

16 The next problem, as Danielle mentioned, is we
17 believe there should be some competitive test or solution
18 test that tries to identify whether there's sufficient
19 bidders or not. Not everybody goes this far, at least, not
20 in what I call near real-time like hourly or daily. Some
21 people have done studies that last 5 or 10 years forward.

22 And lastly, we need to make sure the bids are
23 above some competitive cap. When I say a competitive cap,
24 it's a cap associated with that local market power condition
25 or the real value of that. Having said that, we need to

1 develop that standard. We also need to provide price
2 signals that incent a long-term market solution to solve
3 those constraints that we're worried about where there is
4 the potential to have market power. We've had a lot of
5 discussion on this issue that the compensation to generators
6 or suppliers needed for reliability should be consistent
7 with the competitive outcome, and I would add for that load
8 pocket.

9 I want to point out that competitive outcome
10 isn't necessarily the same, as some have said, as the same
11 competitive outcome as when you have an unconstrained case
12 with no constraints. Those are different levels of
13 competitive outcome to me and we've mentioned the
14 compensation for that also should recognize that those units
15 in that load pocket provide a unique and valuable service.

16 Reliant has offered, I believe, in different
17 dockets, two different ways to solve this. Our current
18 approach is what we call a "systems survey unit" which looks
19 at the highest priced unit in the system on an annual basis
20 and establishes that cost as the cost of the cap in all load
21 pockets. The other way we've approached it is one the
22 Commission had adopted previously as a proxy new entry CT,
23 which is more of an administrative approach. However, it's
24 still probably a good way to do it. So either a systems
25 survey, which is more of a market approach or some

1 administrative approach with a proxy for a new entry.

2 Lastly, our third principle is you need to
3 provide an exit strategy. No matter how well we can set the
4 price or set a cap for those that might have market power in
5 that load pocket, we will miss on some units and that those
6 units that are inefficient will not recover their money and
7 they should be allowed to retire. And we need, I think, for
8 fairness and for reliability to develop a proper exit
9 strategy that could lead to an auction that actually, one,
10 provides the corrected measures for that strategy and also
11 it values the exit strategy.

12 We had some discussion earlier on who does the
13 auction. I think it's somebody that's a dependent. Having
14 said that, I always felt the RTO should do it. Other
15 independent parties could also do that. I think Danielle
16 pretty well covered the ERCOT situation. I might just
17 mention that the competitive solution test that was utilized
18 there was three unaffiliated bidders where no one is
19 pivotal. That was actually done. We intended it to be done
20 prior or ex ante. It was actually done ex post, very ex
21 post in settlement. It had limitations as Danielle
22 mentioned. One, because we had portfolios zonal bidding
23 with option unit premium bids that kicked in for the
24 competitive test. That proves somewhat unworkable.

25 The other large problem we had with it, as she

1 mentioned, is we had an inappropriate allocation of costs
2 which basically spread and muted all the signals and that
3 compounded the problem of trying to create adequate
4 behavior. So I think some of those lessons need to be
5 considered, of course. LMP is a jump start compared to
6 zonal bidding. With at, I'll stop for now and try to answer
7 any questions on other items.

8 MR. COLEMAN: Thanks, John. Next we have Judi
9 Mosley, Director of Wholesale Customer Relations at Pacific
10 Gas and Electric, and similarly, I believe, has been
11 involved in a number of the RMR contracting implementations
12 in California. We're glad to have you here, Judi.

13 MS. MOSLEY: Thank you. It's good to be here.
14 We've heard a lot today about different things we should do
15 in the market to correct the problems of local market power.
16 I'm not an economist and I'm not going to wade into that
17 debate, but I do want to say that that is the place to fix
18 this problem.

19 I come here today with a different perspective.
20 I come here today to talk about some of the experiences that
21 PG&E has had with RMR contracts and some of the
22 frustrations, quite frankly. So I'm hoping you'll agree
23 with me that the RMR contracts should only be used as a last
24 resort. We've really got to get the markets right first.
25 The use of our RMR contracts has been very widespread in

1 California anyway. And while the older units may require an
2 RMR contract in order to keep running in a load pocket, it
3 seems to us that RMR contracts aren't really necessary for
4 the newer and more efficient units. Those units should be
5 encouraged to participate in the markets and get their
6 energy to the market in that way. If a unit is economic,
7 there is no reason to assume that it wouldn't be running
8 under normal circumstances.

9 I wanted to go into a little bit more detail on
10 the particular RMR contract structure we have in California
11 and some of the problems that that's caused. There is two
12 types of RMR contracts in California. Under the first type
13 a generator receives an availability payment to compensate
14 it for keeping the new unit available. Then when it's
15 dispatched, it also gets a predetermined valuable cost
16 payment.

17 Under the second type of contract, however, the
18 generator is actually removed from the market. The
19 availability payment it receives from the ISO covers the
20 unit's full fixed costs. This second type of contract,
21 which is known as "Condition 2" has caused some really
22 insidious market distortions in California.

23 First, by removing these units from the market,
24 it actually increases the scarcity of generation which
25 increases the cost of generation on the market, including

1 energy from other plants owned by the same entity. But
2 second, customers can actually kind of wind up paying twice,
3 and I'll tell you what I mean by that.

4

5

1 The Condition 2 units have been removed from the
2 market, they're not producing energy and ancillary services.
3 Consequently, PG&E is required to go out and procure energy
4 and reserves from other units, even though PG&E's customers
5 are paying the full fixed costs of those units, the
6 Condition 2 units that are largely idle.

7 As the Commission recognized in the Devon Power
8 case last year, RMR agreements should be a last resort and
9 the proliferation of these agreements is not in the best
10 interests of the competitive market. We agree
11 wholeheartedly with that sentiment, particularly when it
12 comes to these Condition 2 agreements, and we urge the
13 Commission to eliminate these types of contracts.

14 The Commission has gone to great lengths to
15 establish and support competitive wholesale energy markets.
16 We think that, to the greatest extent possible, we need to
17 support those markets by requiring that units run in those
18 markets, rather than subsisting solely on the RMR payments.

19 Although I'm not going to get into the details of
20 pricing in the market as a whole, I do want to talk a little
21 bit about the pricing of RMR contracts. I think the guiding
22 principle really needs to be one of neutrality. RMR
23 generators should be no better off and they should be no
24 worse off than other generators.

25 So, under the net incremental cost approach, RMR

1 generators are compensated for all costs associated with RMR
2 obligations. So, for example, if you do have a older
3 uneconomic plant that is needed to run to support
4 reliability of the grid, they will be paid an amount
5 sufficient to cover the shortfall between what is forecast
6 to recover in the market, if anything, and its ongoing cost
7 of operations.

8 If it can make more in the market, it keeps the
9 profits. That way, it has every incentive to participate in
10 the market. The advantage to this approach is that RMR
11 owners are compensated for all of the costs of RMR
12 obligations, local market power is mitigated because there
13 is no monopoly rents. RMR owners are encouraged to
14 participate in the market, and they don't have a competitive
15 advantage over other generators.

16 There is one other issue that I think merits
17 consideration today. Once you figure out the best way to
18 price an RMR contract, you still have to figure out who
19 should bear the cost. Pursuant to the Commission's efforts
20 to eliminate rate pancaking, PG&E's transmission costs are
21 spread to all users of the California ISO system, but RMR
22 costs are borne exclusively by PG&E's customer. To us, this
23 seems inequitable, because RMR contracts, the units were
24 installed as a cost-effective alternative to transmission,
25 and those RMR units are need to support reliability of the

1 grid. So, to the extent that we really need to have RMR
2 contracts, we think we need to take a really hard look at
3 how those costs are spread to customers. With that, I'll
4 conclude my remarks and address questions at the end.

5 MR. COLEMAN: Thanks, Judy. We'll turn next to
6 Keith Casey from Cal ISO. Keith?

7 MR. CASEY: Thank you, Mr. Coleman. I'd like to,
8 first off, thank the Commission and Commission staff for
9 holding this conference. It's a pleasure to be here to
10 provide California ISO's perspective on this very important
11 issue. It's extremely important to California as we move
12 forward with our new market design.

13 The disadvantage of going so late in the day is
14 that it's hard to be original. The advantage is, it is an
15 opportunity to build off of some of the comments I've heard
16 from the previous speakers.

17 Several points have been made today that I agree
18 with, and I would like to reinforce them, and there have
19 been some points that I don't agree with and would like to
20 explain why.

21 We heard a lot today about getting the prices
22 right, and there are a few points that I would like to make
23 about that. I wholeheartedly agree with Mr. Bowring from
24 PJM that, absent physical scarcity, the correct price is the
25 unit's marginal cost of production. I think that's a

1 standard that most economists would agree with.

2 I wholeheartedly agree with the concept that you
3 can have market power problems in load pockets, but not have
4 scarcity. You can have an abundance of generation, but it's
5 owned by one generator owner, and they are able to exercise
6 market power, so you need to discern true scarcity from
7 market power.

8 We support the concept of physical scarcity in
9 developing pricing rules during periods of scarcity. In
10 fact, our proposed ND02 design actually does have an element
11 of scarcity pricing. Some of the concepts proposed today
12 relating to scarcity when operating reserves drop below a
13 certain level, perhaps has some merit, but I think there's a
14 lot of things that need to be worked out to really iron out
15 whether that approach has merit.

16 High prices or the threat of high prices are
17 necessary to incent new generation. We've heard that a lot
18 today. The story basically goes that load-serving entities
19 aren't going to enter into forward contracts unless there's
20 the looming threat of high prices, if market conditions
21 deteriorate, and, as you heard today, suppliers is not going
22 to build new generation unless they have the ability to do
23 forward contracts.

24 I think this concept makes a lot of sense when
25 it's applied on a regional basis where entry is relatively

1 easy. Entry does not necessarily have a significant impact
2 on market prices. Where I think that concept falls down
3 somewhat is in highly isolated load pockets where entry is
4 extremely difficult and where entry, to some extent, will
5 have an impact on reducing market prices.

6 It may lead to the type of market failures that
7 Mr. Hogan spoke of. Again, the concept of the need for high
8 prices to attract investment, it can work on a broad
9 regional basis to address regional needs.

10 We don't think it's particularly applicable in
11 isolated load pockets, so if high prices in load pockets are
12 not the answer, what do you do to ensure adequate
13 infrastructure in lieu of profits? I think the answer to
14 this really lies in getting straight, who is responsible for
15 reliably serving load?

16 In California, that obligation lies largely with
17 the utilities, the major load-serving entities in
18 California. And when you think of it, local scarcity is a
19 reliability problem. Scarcity and reliability go hand-in-
20 hand. In fact, as we sit here today at this conference,
21 some 3,000 miles from here on the West Coast, there are a
22 bunch of people in a PUC hearing room, discussing
23 transmission projects for San Francisco, and the need for
24 those transmission projects.

25 And in those discussions, they're debating the

1 merits of a new transmission line, relative to building new
2 generation. The impact, environmental and social, of
3 building that generation, whether to retire older, less
4 efficient barrier units, whether you can avoid all of that
5 through energy efficiency programs, demand response, my
6 point is that in load pockets, the issue of providing the
7 infrastructure is a huge public policy issue with large
8 social and environmental implications, and it's a very long
9 and timely process.
10
11

1 MR. CASEY: So, the main piont being that given
2 in that context is having high prices and load pockets gonna
3 help bring about the needed infrastructure and I would argue
4 that, if today that debate was happening and the prices in
5 San Francisco were \$1,000 every hour, those prices would in
6 fact detract rather than help bring about this needed
7 infrastructure.

8 Again, ultimately, with respect to infrastructure
9 and load pockets I believe it is a local resource adequacy
10 problem best addressed by load-serving entities.

11 So how do you get, how do you get the
12 infrastructure in the load pockets? The best approach is
13 through long-term planning, through long-term capacity
14 requirements.

15 And the recent order issued by the PUC, while not
16 all that we would have hoped, at least from the ISO's
17 perspective does provide a framework and something to start
18 from in terms of defining locational capacity requirements
19 and incorporating those into the utilities procurement
20 plans.

21 The key there is to address local market power
22 problems, simply shifting an energy market power problem to
23 a capacity market, moves the market-power problem to the
24 capacity market.

25 I think that process needs to be forward-looking

1 enough several years out so that there are a lot of options
2 that the load-serving entity could enter into to mitigate
3 the local market power concern. So I think there's promise
4 and potential for load-serving entities, through the
5 procurement proceedings at the UC to meet local reliability
6 infrastructure needs. That's the best venue for it.

7 Again, just to quickly summarize the high LMP's
8 and load pockets are not really the solution. We favor very
9 aggressive mitigation for energy bids in local market power
10 situations. Scarcity pricing has merit, but more work needs
11 to be done to define where, how, and when scarcity pricing
12 takes place.

13 Most importantly, when you have aggressive local
14 market power mitigation, it's critical that the units in
15 load pockets are able to recover the full fixed cost.
16 Ideally we think long-term contracts with the utilities is
17 the best way to address that.

18 But ultimately I think RMR contracts do have a
19 role in the future design as a backstop in the event that
20 the contracting doesn't occur or certain units are missed to
21 make sure that we are able to catch and provide the revenues
22 necessary for those units to recover their cost.

23 My last comment: The worst solution from the
24 local market power standpoint is to incorporate fixed cost
25 recovery through bid adders to the variable costs of units

1 as part of mitigation. We think that's a very imprecise
2 tool that is most likely going to lead to certain generators
3 getting way more revenues than they need to recover their
4 fixed costs and others not getting enough.

5 With that I conclude and look forward to your
6 questions.

7 Mr. COLEMAN: I appreciate your comments, Keith.

8 We have next a man who has been very busy doing
9 his own stakeholder process. He's out in the Midwest ISO.
10 We have Ron McNamera, Vice President, of Regulatory affairs
11 and chief economist at the Midwest ISO.

12 I appreciate your taking the trip here to be with
13 us today.

14 MR. MCNAMERA: Thanks again to the Commission for
15 asking us once again to represent the MISO and our budding
16 market out there.

17 I apologize I wasn't here earlier. So maybe I
18 missed some things and I will be redundant. I didn't have
19 the benefit as Keith did in terms of -- and I'm sure I'm
20 going to reiterate some of the points they made.

21 I'd like to start by saying I'll take as a given
22 that everybody understands the importance of getting the
23 market design correct, that we do -- actually having gone
24 down many different pathways and many different intellectual
25 excursions that we do pretty much have a good idea as to

1 what works and what doesn't.

2 And I think that has to form a fundamental basis
3 for any mitigation plan that we actually have -- a robust
4 market design that underpins that and lays the foundation
5 for that. By that I mean basically centralized, security-
6 constrained economic dispatch relying upon LMP.

7 I think when I hear terms like "in the market" or
8 "be in the market" or "out of the market," that's where
9 question marks start to come in the back of my head. You
10 can be in the market. You can be out of the market. But
11 you're always going to be a dispatch.

12 And there's always going to be an LMP price
13 produced. And the price is going to bring transparency and
14 it's going to fundamentally link the commodity to the
15 delivery side of things, which is so vitally important to
16 getting the signals right all the way up and down the chain
17 from the forward markets into the real time when the product
18 actually goes physical.

19 It would be great if electricity had some kind of
20 better storage properties so that we could kind of have a
21 gas market type of thing where we could really separate
22 delivery from the commodity. But we don't.

23 Electricity doesn't behave that way. And so
24 linking the delivery mechanism to the commodities is
25 fundamental to the new market design.

1 That being said, I would then like to diverge a
2 little and say from the economist's standpoint when I look
3 at market power, really I look first to a commercial
4 solution.

5 Why can't we get a commercial solution in this
6 situation? Usually what you get back is well, I can get a
7 commercial solution. I just don't like that commercial
8 solution. At least one party says that.

9 I think where we then end up is we don't actually
10 evaluate essentially the economic properties of that
11 solution vis-a-vis the alternative properties in terms of --
12 by going down and recommending increasingly onerous
13 mitigation procedures. What are the kind of welfare
14 properties that result from those in terms of a long-term
15 investment and consumer behavior? and so on and so forth.

16 And I think it will be useful to essentially have
17 some sort of test. We've actually looked -- we're already
18 in this world of second best. Which is the worst of the
19 two? Which is the best of the two? Really if you look at
20 it from the standpoint of a commercial solution and you kind
21 of take that line of thought, then you go down the path of,
22 well, really market power represents a loss or manifests
23 itself as a loss of leverage by one of the parties.

24 Really what's happened is choice is restricted;
25 the options aren't available. And that really in effect

1 reduces leverage that one party has due to negotiation.

2 Really what we should be looking at for the long-
3 term solutions, I'll echo the sentiment that John Meyer made
4 earlier in terms of short term versus long term.

5 Is this a temporary problem? Or is this a long-
6 term problem? I think the greatest welfare game from
7 eliminating this over the long term as opposed to the short
8 term.

9 What I'm addressing more is, what's the long-term
10 solution to this? And in effect how do we increase the
11 leverage that parties have so that it's somewhat symmetrical
12 in this. And then we have to define that path at the
13 beginning.

14 One party has a loss of leverage. What's the
15 part cost of whoever increased their leverage and who pays
16 to increase their leverage? I think that's where we have to
17 ask the question of what role does market design play --
18 i.e., price caps and RMR contracts and so on and so forth.
19 How does that in the long run actually increase the leverage
20 the other party has?

21 I guess what I'm alluding to here is the fact
22 that market power is in some ways very difficult to define.
23 I do believe we have markets where there's monopsonistic
24 power. We tend to focus overly on the sellers' side as
25 opposed to the buyers' side. I think that's something that

1 needs to be looked at.

2 I also think we have to recognize that there is a
3 fundamental problem. It's not a bad problem. It's just a
4 real problem. And this is you have assets going in the
5 ground that are essentially making the long-term decision
6 20, 30, 40 years out. And you have buyers that are buying
7 short-term every single day.

8 You have a problem as there the supplier is
9 supplying long and the buyer is buying short. That's going
10 to create essentially a disconnect there. And I'm not sure
11 how price caps necessarily resolve that problem.

12 They may resolve it in the very near term. But
13 this gets back to what I would criticize in that there seems
14 to be an infatuation with the spot market when in fact the
15 spot market, as almost any mature electricity market,
16 represents a minority of the sales, not a majority of the
17 sales.

18 With that I'm going to use my time and turn it
19 over to my stakeholder.

20 MR. COLEMAN: Thanks, Ron.

21 Our last speaker on this panel is Steve Beuning
22 from Xcel Energy. Thanks, Steve.

23 MR. BEUNING: Ron, you took that right down to
24 the last second. That was perfect.

25 I'm with Xcel Energy, one of our operating

1 companies. Northern States Power is located in the Midwest
2 ISO footprint, so it's my pleasure to work with Ron. It's
3 also my pleasure to be here with a chance to talk to you
4 all.

5 We have a generating station in northern
6 Wisconsin on the south shore of Lake Superior that's
7 necessary to be on line and in peak periods to prevent a
8 blackout from loss of a transmission element.

9 That area reliability that it supplies has to be
10 there about half the hours of the year. So this grid
11 operating guide compel us to put this unit into the dispatch
12 mix out of merit order.

13 Does that generator have market power? I'd say I
14 haven't given you enough information yet to conclude that
15 because you don't know if I'm putting the costs for that
16 generation onto some other party in an inappropriate way.

17 As long as it's all my own load in there and it's
18 all my own generation in there, in that load pocket one
19 could argue that that's not a situation that would even be
20 applicable for a market power calculation.

21 I wanted to just get right to the summary of my
22 points. Then I'll digress back into some of the detail
23 given the late hour here.

24 But I guess in the long run the development of
25 transmission facilities that are economically efficient and

1 environmentally acceptable would increase reliability.

2 If you had a load pocket, it would expand the
3 pool of available resources to supply that load. It would
4 increase market access for generators who reach those loads.

5 But until you've solved that problem in that way
6 -- and by the way, if you did solve the problem in that way,
7 you'd be allocating the costs to people through transmission
8 rates.

9 Until you've solved the problem that way, you've
10 got a situation where generators that are critical to long-
11 term good reliability should be getting compensation that
12 meets some principles.

13 The compensation should be no less than something
14 like the greater of the regional market clearing price or
15 their own long-run costs. Plus there should be a
16 consideration for the value of the transmission deferral
17 that that generation operation has made possible.

18 In the load pocket we've got infrastructure
19 lacking by definition. It's just unreasonable that the
20 financial support to the generation in that load pocket
21 should be commensurate with the infrastructure requirements
22 to serve those loads.

23 And we shouldn't be scaring investors and
24 operators away from that load pocket with the threat of
25 price mitigation. That valuation of the transmission

1 deferral could be performed by the RTO as part of a regional
2 planning process.

3 The additional consideration provided to the
4 generating units perhaps could be based on that. We've got
5 cost allocation in this part of the discussion and maybe
6 we'll want to talk about it a little bit more.

7 Now, maybe we're talking about something that's
8 not getting cross-allocated as part of transmission rates.
9 But if we're given the fact that this unit is necessary for
10 reliability and that that's going to be increased costs over
11 the basic market-clearing price, how do we spread or
12 allocate those costs?

13 If I start with a load pocket definition like
14 this, it's an area of the grid where a binding transmission
15 constraint requires generation in the local area in order to
16 maintain post-contingency delivery to loads.

17 And then I just wanted to add a distinction. I
18 think a load pocket is not the same as a generation pocket,
19 which I don't hope we address today because a generation
20 pocket presumably would be something solved through order
21 2003 implementation in the future.

22 I want to talk for a second about how we did it
23 in the old days. We used to administer our network tariff
24 at Northern States Power that was pre-RTO. In that
25 situation we took the costs of redispatch and allocated them

1 to the parties to the network tariff.

2 We had something like a local uplift phenomenon.
3 But I would submit to you that in the case of a large
4 regional network tariff that would not be an equitable
5 situation for the following reasons. The uplift costs could
6 be incurred in the area of the grid where the party paying
7 the costs has no voice in the planning, construction, or
8 operation of the grid elements.

9 The parties being uplift can't rationalize those
10 costs as a trade-off against their own costs of transmission
11 construction.

12 And there's too much lag between the point in
13 time that you identify the problem and the transmission
14 construction solution.

15 So if we're going to allocate the cost under the
16 RTO's network tariff, what are some of the things we might
17 want to think about?

18 We might want to have identification of load
19 pockets bubble up through -- lie along between the
20 reliability authority, the grid operator, and the regional
21 planning process.

22 We might want to stipulate operating response for
23 a generation in the load pocket in public documents as
24 parties' operating procedures that recognize that plant
25 output is variable and the plant availability is not to the

1 same degree as transmission facilities' availability. We
2 try and identify and develop those costs on a market basis
3 to the extent possible.

4 I do think that for long-term load pocket
5 problems we could be fairly precise in the identification of
6 those areas as part of the regional planning process.

7 Let me skip around because I'm out of time. I
8 guess if we get the planning right, I think we'll be able to
9 follow the cost allocation properly in the long run.

10 And I just wanted to reiterate that I think --
11 Virtune recognized that supporting costs for a generation in
12 load pockets is a more valuable service than just the
13 generation cost because they've got that avoided
14 transmission investment and increased reliability in the
15 area that's making it possible.

16 I'll cut it off at that. Thanks.

17 MR. COLEMAN: Thanks, Steve.

18 I have a question for Keith. If I heard
19 correctly, you were saying that the market design and the
20 spot prices that this Commission is responsible for you
21 think should not really reflect scarcity and some of the
22 high priced aspects that we heard about this morning in the
23 California market design, but rather await the state
24 resource adequacy approach and allow that to take care of
25 the problem while we sort of mitigate the price signals that

1 would otherwise be coming out of those areas if we followed
2 the principles being discussed this morning. Is that
3 correct?

4 MR. CASEY: With respect to whether you'd allow
5 any scarcity pricing in a load pocket, our MDO-2 - for those
6 of you not familiar with our vernacular, our new market
7 design for California, our LMP market design -- does
8 propose that if there is truly a physical shortage, that
9 there's insufficient supply to serve load, that prices would
10 be allowed to rise to the price cap. In that context the
11 design does allow for scarcity pricing.

12 What we've not contemplated under the design is
13 what Dr. Patton talked about -- scarcity pricing. If
14 operating reserves in the load pocket drop below a certain
15 level -- again, that's a relatively new concept that I think
16 needs to be flushed out of it more to understand how you can
17 implement it in the context of the design and how frequently
18 it would be hit.

19 The big concern we have is because of the
20 extensive time it takes to develop infrastructure in highly
21 concentrated load pockets, whatever scarcity pricing
22 mechanism we have, if it's being applied every hour for
23 several years, the dollars are going to start adding up.

24 I think you have to be cognizant of the fact that
25 there is a much longer planning horizon for meeting local

1 infrastructure needs than would be the case on a more
2 regional basis.

3 MR. PERLMAN: I'm really asking a different
4 question, sort of a macro policy question. I read your MDO-
5 2 filings. I'm familiar with them.

6 I got the sense you were saying that a lot of RMR
7 contracts -- we have the CDWR contracts. We have other
8 things that take these power plants effectively out of the
9 spot market. And you used the three percent transacted
10 through the spot market in your filing.

11 What I got from that was, don't worry about
12 getting the market right because it's really not that
13 important if we're going to allow the other aspects of the
14 market to work. So let's just keep the prices low in the
15 spot market and let's address the spot market as sort of a
16 balancing market.

17 Is that a mischaracterization of what you've
18 filed?

19 MR. CASEY: I think it's an incorrect
20 interpretation of the arguments we made in that filing.
21 We're arguing that mitigating unconstrained areas to unit's
22 marginal cost is getting the prices right. Because in our
23 view allowing prices to go above those levels, absent
24 physical scarcity, I don't understand the economic rationale
25 for that.

1 MR. O'NEILL: In order to qualify that, you said
2 physical scarcity. Does that include operating reserves?
3 In other words, if there's physical scarcity of energy plus
4 operating reserves, would you consider that a physical
5 scarcity?

6 MR. CASEY: That's an issue we would have to take
7 a look at. As I have said, with respect to if there's truly
8 insufficient supply to meet load, you're having to curtail
9 load.

10 MR. O'NEILL: I would think that NERC would
11 consider that a physical deficiency.

12 MR. CASEY: We would agree. When you talk about
13 operating reserves dropping below a certain level, that gets
14 into a grey area in my mind that we would have to take a
15 closer look at to see if that's a viable approach.

16 MR. O'NEILL: It's not so grey for reliability.

17 MR. CASEY: That's true, but reliability isn't
18 black and white. There are variations of reliability risk
19 and whether that's truly physical scarcity.

20 MR. SINGH: Stage 1, 2, and 3 -- all of them are
21 not on the table for scarcity pricing I guess.

22 MR. CASEY: As it's proposed in our design,
23 that's correct. I'm not ruling out the concept of applying
24 scarcity pricing if reserves drop below a certain level in
25 load pockets. It's just simply one has to look at how you

1 would implement that approach and what are the potential
2 impacts of it in terms of how frequently do you bind in.

3 MR. O'NEILL: Isn't that a good signal for load,
4 when you're in one of these reliability stages that sees the
5 price go up?

6 MR. CASEY: I think the most important signal for
7 load is that you have a regulatory obligation to keep the
8 lights on to serve load.

9 MR. O'NEILL: We would love to see that happen,
10 but we're not sure it will.

11 MR. BANDERA: Keith, just to maybe jump in, would
12 you say that you might agree that an operating reserve
13 shortage is a physical shortage, but in terms of scarcity
14 pricing as you jump right into MDO-2, you might be more
15 concerned that the cost shifts that occurred before any
16 needed investment could come in could be overwhelming and
17 you would prefer a type of mechanism that would be phased in
18 over time? Or do you think that it would never be
19 appropriate?

20 MR. CASEY: I would say -- and again, in terms of
21 representing the ISO's views, I can only speak to what we
22 filed in our design. That said, I'm offering this on this
23 issue.

24 I would certainly be open to evaluating a
25 scarcity pricing under an operating reserve threshold. But

1 there's a lot of information we would have to develop on how
2 that would work and the sensitivity to the fact that you'd
3 have to recognize that meeting infrastructure needs in
4 densely populated areas is a very slow litigious process.
5 And you have to design your policy.

6 MR. BANDERA: One last thing. Before your
7 opening remarks you made a comment stating that sort of
8 reliability was the state and the local utility's
9 responsibility, not necessarily the ISO's responsibility.

10 Earlier today we heard comments about wholesale
11 market design rules. Should we stand alone in a sense and
12 not be held captive to sort of retail structures that are in
13 place on a state-by-state basis?

14 Do you think that there should be a sort of a
15 case-by-case basis on the retail structure and how the
16 reliability of each is responsible for the terms of
17 designing those wholesale market rules? Or do you think
18 they need to do it independently?

19 MR. CASEY: I think there has to be some
20 flexibility and deference to, you know, regional wishes in
21 terms of the scope and scale of the RTO's functions,
22 particularly in the area of resource adequacy.

23 You've heard Mary Strongly from California that
24 they view resource adequacy as a state issue. I don't know
25 if that answers your question.

1 MR. TIGER: I'd like to ask a question of Mr.
2 Meyer with regard to maybe a little bit of a clarification
3 as to the exit strategy option -- whether you could expand a
4 little bit on that.

5 MR. MEYER: Okay. The exit strategy we had in
6 mind -- when we're talking about exit strategy, the exit
7 strategy option differs a bit from the PJM proposals they
8 described earlier this morning.

9 Their decision is more what I call looking ahead
10 or a transmission planning. Or a network design type
11 function is you look ahead and there's inadequate capacity
12 to serve the area reliably. You either bill transmission or
13 create an auction to entice new generation if you're not
14 sending proper price signals. What I was talking about is,
15 for instance, as Keith just mentioned, his view is that you
16 only pay marginal costs to generators in a load pocket for
17 providing a service. I stated you should pay well above
18 marginal cost -- just make sure that you have enough money
19 to stay there.

20 But if you pay marginal costs, it's a political
21 or policy decision, but you've got a lot of -- but you can't
22 say I'm only going to pay your costs. You may not recover
23 your needed revenues. But you're going to stay here anyway
24 because basically you're creating an obligation to serve.

25 What the auction tries to do is two things.

1 While you're leaving for reliability, it tries to
2 immediately find the outcome that's most efficient --
3 number 1 -- which could be transmission generation or load.

4 Number 2, it tries to value what that's worth.
5 As someone suggested, you should pay part of that because
6 that's really part of the rent, that extra value that unit
7 may provide to that area.

8 We believe that auction does those two things.
9 It values the avoided costs for what service costs you're
10 providing, number 1. And it finds the most efficient
11 solutions. So that differs where I'm reliability short and
12 I must do something such as build transmission.

13 MR. TIGER: You're basically finding out the
14 value of the opportunity cost or the fixed cost essentially
15 through some process and that's administered presumably by
16 an independent party.

17 MR. MEYER: I'd say an independent party. To me
18 it should be probably the RTO or ISO. But we want to make
19 sure he has an independent view of that. It shouldn't be
20 biased in any way.

21 MR. COLEMAN: John, does that give you the
22 opportunity to go into those markets where you say I want an
23 exit strategy?

24 If we were willing to pay you your long-run
25 marginal cost, you may say, well, we'd like to have someone

1 evaluate what, I guess, the replacement infrastructure would
2 be to you. And if that's higher, aren't you holding us
3 hostage in terms of saying, well, I'd like to get that high
4 a price even though --

5 MR. MEYER: If you're paying me my long-run
6 marginal cost, I'm not sure why I would suggest I'll
7 retire.

8 MR. CASEY: If I could just add to that. John
9 picked up on the first point of my statement, which is we
10 believe the short-run marginal cost is the right price
11 signal absent physical scarcity.

12 But the second point was that absolutely units
13 that are critical to providing local reliability services
14 need to have their going forward fixed costs covered. And
15 the best mechanism for doing that is a long-term locational
16 capacity obligation.

17 We weren't suggesting to strand units without
18 adequate compensation.

19 MR. PERLMAN: I have a question on that
20 retirement option. If you're going to retire the unit -- I
21 guess, if you're going to exit the market, someone is going
22 to come in and take your place if there's reliability
23 concerns. And there will be a transition period I assume.

24 MR. MEYER: They might.

25 MR. PERLMAN: As soon as you're free to exit the

1 market, you don't want your asset anymore. Would part of
2 that offer of exit be that you would make your existing
3 asset available, let's say, at book value for others to take
4 over if they were to come in and replace you and do some
5 sort of reliability project? So therefore you wouldn't have
6 a leg up. Everybody's competing on the same place.

7 MR. MEYER: I think you've asked me this before
8 in other forms.

9 (Laughter.)

10 MR. PERLMAN: But not in a public one.

11 (Laughter.)

12 MR. MEYER: We have cases -- I believe a plant in
13 California -- where the market value of the land exceeds
14 the book value probably by 10 times.

15 MR. PERLMAN: Let's say a higher book or market
16 value.

17 MR. MEYER: I think they would probably sell
18 that. I don't know why anybody would just walk away from it
19 and make a rational business decision. But they will exit
20 the market if they can't sell it.

21 If you can't earn the money, I'm not sure how
22 anyone else can earn the money. But yeah, I would sell it
23 for an adequate value. No reason not to.

24 MR. TIGER: Would Dr. Newman care to buy it? I
25 guess maybe you could talk a little bit to the degree of

1 which now you've had the benefit of some of the conversation
2 about what the necessary conditions would be for you to
3 invest in generation.

4 MR. NEWMAN: I have two minutes saved up, right?

5 (Laughter.)

6 MR. NEWMAN: Sure. I listened to this
7 conversation about mitigation and in part it makes my blood
8 run a little bit cold. I would refer to that as the "theory
9 of the second yes" rather than the "theory of the theory
10 best."

11 You're asking somebody who comes in here to put
12 his capital at risk whenever markets tighten up, which will
13 take away the opportunity to earn a return on that. I think
14 that's difficult.

15 So the short answer to your question is, if
16 you're asking me to rely on volatility to get paid a return
17 on capital, I find that a very uncomfortable situation. And
18 I listen to this conversation and it's all focused in terms
19 of well, when prices exceed your marginal cost, that's a bad
20 thing.

21 And I keep asking myself, isn't capital a
22 marginal cost somewhere in here. Why do I get my recovery
23 of my capital? I'm investing on behalf of pension funds.
24 They're expecting me to produce a return for them.

25 If the only thing I want to get back is my

1 marginal costs at some point, I'm going to be looking for
2 something else to do. And I find that a pretty
3 uncomfortable position for us to be.

4 So I think a focus on volatility is an
5 uncomfortable place for us to be. It makes me much more
6 comfortable, so I would buy John's plants, but I need some
7 sort of contractual protection there for the capital.

8 My reaction is if you look at contractual
9 capital, you can get long-term capital and long-term capital
10 tends to be much cheaper than short-term capital because you
11 can recover it over a much longer period of time.

12 In fact, I've always found it interesting -- this
13 focus on relying on volatility to recover capital costs --
14 because it forces you to attract capital who is comfortable
15 getting that kind of return, which tends to be very short-
16 term, high return capital, the stuff that trading desks do,
17 not the stuff that institutional investors do.

18 The short answer to your question is: I don't
19 like relying on volatility to buy Mr. Meyer's plant. And if
20 you were to offer it to me in a world where I was constantly
21 being mitigated and reduced to perhaps my energy margin,
22 there's a price I would buy it, but it is unlikely to
23 recover his market or capital costs.

24 MR. BANDERA: It sounds like both the sellers of
25 energy don't want to see volatility. They would like to see

1 some more certainty. And the buyers would like to see more
2 certainty. And that when you have this spot market regime
3 with the volatility, it seems to give both of those people
4 the incentive to work together to eliminate that volatility.

5 MR. NEWMAN: My understanding -- there are some
6 regulatory and other issues with that in some circumstances
7 if the buyer is contracting long term and they guess wrong,
8 they are penalized for it.

9 There has to be some recognition of the insurance
10 and other aspects, whereas you've talked here that you view
11 reliability as a product. It ought to be priced as a
12 product in that regard.

13 I think the economists like volatility, but the
14 marketplayers don't.

15 MR. CASEY: One point of clarification. I wasn't
16 suggesting in my comments that prices during nonscarcity
17 periods should never exceed the marginal cost of units. My
18 point was that price should reflect the marginal cost of the
19 highest cost unit needed to serve load in that.

20 It would certainly be the case if we had a brand
21 new highly efficient combined cycle, that the prices being
22 set by a 40-year-old coal unit -- there are some infra-
23 marginal rents that your efficient unit would be able earn.

24 MR. NEWMAN: Whether those are sufficient or not?

25 MR. CASEY: Whether those are sufficient to cover

1 your fixed costs is a valid point and that's why in my view
2 you have to supplement that type of mitigation with an
3 opportunity through a capacity market to acquire additional
4 revenues.

5 MR. O'NEILL: If we don't let the spot market
6 clear properly, how can we evaluate whether or not the
7 resource adequacy, which is a CPUC decision, adequately
8 compensates the generators?

9 MR. CASEY: In the case of California, we're not
10 proposing a formal long-term capacity market. What we're
11 proposing is that the requirements be established by the
12 Public Utilities Commission working with the utilities.
13 Then they would contract bilaterally to meet those needs.

14 In that case each party would bring to the table
15 their respective positions. If they strike a deal, then the
16 generator entering into that agreement voluntarily -- you'd
17 have to argue I believe they can recover their fixed costs
18 with that capacity payment.

19 MR. O'NEILL: But how do we know that? Are we
20 going to ask you to file all those contracts so we can read
21 them?

22 Shouldn't it be better just to make the spot
23 market clear properly and the people who are long and have
24 contracted long benefit from the spot market prices if they
25 are high? And if the people who are short and told us that

1 they are really long see high prices, then it's because they
2 thought they were long and they weren't.

3 MR. CASEY: I guess the question is, should we
4 let the spot market clear properly? If that means don't
5 apply local market power mitigation, let the prices be what
6 they will. I don't see how that --

7 MR. O'NEILL: It's local market power mitigation
8 with appropriate scarcity prices.

9 MR. GRAMLICH: In terms of what an appropriate
10 price is, Danielle mentioned an interesting case in ERCOT
11 where additional supply came on and the price went up. Is
12 that what you'd see in a competitive market? You wouldn't
13 see that if you had scarcity pricing.

14 MR. CASEY: I don't see how in a load pocket you
15 have additional supply committed to that market.

16 MS. JAUSSAUD: This is a generation pocket.
17 That's why the price went up.

18 MR. GRAMLICH: In PJM I was -- maybe ERCOT is
19 designed just fine. I was going to say this happens not
20 just in ERCOT, but it does happen in PJM and elsewhere. If
21 the price-clearing mechanism is the generator's supply bid
22 at all times, then you can have a situation where increased
23 supply raises the price, which is not what is supposed to
24 happen.

25 MR. CASEY: I don't see how that would happen

1 unless you had some other lower cost units that became
2 unavailable.

3 MR. BANDERA: I could come up with an example for
4 you. I start a little wood-burning stove plant in San
5 Francisco. Then when you're in an operating reserve
6 shortage out there, I put in a bid for \$2,000.

7 Let's just say I've got a megawatt here that I
8 can put out for you and then secure an operating reserve
9 shortage situation. You need to take my energy so that you
10 can keep as much reserves as possible.

11 So before they may be in a load pocket, their
12 marginal cost was only \$250. I've got my unit in there that
13 has a marginal cost of \$2,000. My entry of just one extra
14 megawatt at \$2,000 has increased the price from the
15 mitigated price level at \$250 to \$2,000 by adding extra
16 supply, because before we were mitigating to the marginal
17 costs of the unit even though we were short operating
18 reserves.

19 MR. CASEY: We'll have to follow up on your
20 example.

21 MR. PERLMAN: Can I ask Mr. McNamera a question?

22 I heard Mr. Beuning say earlier that in his
23 company and in MISO to some degree you're going to have
24 situations where you have a vertically integrated utility
25 that hasn't disaggregated that's part of the MISO that have

1 load pockets within its service territory, where it has
2 generation load -- both.

3 Is it your view that if it's a vertically
4 integrated utility with retail rates, that it's part of the
5 MISO market that the Commission and the MISO should still
6 undertake with you of that load pocket and do mitigation
7 with respect to the units in that area? Mr. Beuning
8 indicated in his view that that was questionable.

9 MR. MCNAMERA: I think you have to look at it,
10 because there are going to be off systems sales. There's
11 going to be all sorts of things that are going to happen. I
12 think you have to take into consideration who they are
13 selling to and so on.
14 But I do think it has to be part of something.

15 MR. BEUNING: If you define that load pocket as
16 that area that's got the binding constraint and needs the
17 generation inside, if there's exports happening out of that
18 load pocket, then the generation in that load pocket must be
19 a marginal unit.

20 So in that sense I don't know that you could
21 assert that they had market power.

22 MR. CASEY: I guess I would add if they are
23 exporting, then you don't have a local market power problem.

24 MR. MCNAMERA: The question is interesting to
25 look at. Yes, it's got to go through. You don't just

1 ignore it.

2 MR. PERLMAN: I guess there's a different
3 question of whether you ignore it or not. It's a question
4 of is there something different about the MISO structure
5 because of the existence of vertical integration.

6 That's different than other markets we're talking
7 about -- that calls us to consider it differently or should
8 be considered in the same manner and to just go forward with
9 a structure that looks similar, say, to New England.

10 MR. MCNAMERA: So the lack of retail choice in
11 the MISO states necessitates.

12 MR. PERLMAN: Not retail choice, but an example
13 we talked about. You have load and generation owned by the
14 same entity that's serving in effect retail at the end
15 subject to state regulation, so you don't end up with much
16 that's transacted through the wholesale market.

17 But you could have some price signals you want to
18 send or something like that that may cause you to recognize
19 it as a wholesale market issue.

20 In the example we talked about the power isn't
21 being exported. It's being run by a local generator to
22 serve local load and is basically subject to the local
23 commission.

24 MR. MCNAMERA: It has to be contingent on the
25 fact that basically the buyer and seller are the same

1 company. So it's one company.

2 MR. PERLMAN: Which I think is not unusual.

3 MR. MCNAMERA: That may not be unusual. Let's
4 wait and see what the flow patterns are after we start with
5 LMP. I know that those are the flow patterns that may exist
6 today, but I think when you get transparent price signals,
7 there's not a market that's gone to LMP that the flows
8 haven't changed dramatically.

9 MR. HELMAN: Ron, let me ask you ask another
10 question about MISO. Since MISO is going to start as an
11 energy only market, you all have the chance to apply
12 locational reserves or a locational capacity at least
13 initially.

14 Have you looked at whether the New England
15 experience with loosening mitigation at the load pockets --
16 that didn't work at least initially in that summer and may
17 not have worked under many circumstances. Have you looked
18 at how that might affect the particular load pockets that
19 you have -- i.e., whether they are likely?

20 We heard that there wasn't sufficient market
21 power in the load pocket in New England to get the prices up
22 to where they are needed to be. You're going to be working
23 only with the energy prices. Have you looked at those sorts
24 of effects in the other load pockets?

25 MR. MCNAMERA: It's hard to look at it before you

1 get to LMP -- I would say number 1. But I do think we're in
2 a different situation. We do have areas where we have
3 severe constraints. And it is likely that we are going to
4 run into -- that the prices will rise considerably if left
5 unfettered.

6 LSE has been one of the stakeholders involved in
7 this. We do include the effects of reserves on dispatch.
8 And while there is a reserve market, certainly reserves will
9 essentially be explicitly incorporated into the dispatch and
10 will be for added effect.

11 MR. HELMAN: But you won't be able to get a
12 locational reserve price or have a reserve price transferred
13 to the energy market.

14 MR. BEUNING: Can I try and answer this one
15 quickly? While the operating reserves taskforce of
16 stakeholders was meeting at the Midwest ISO to try to
17 establish how things would be handled in the transition into
18 the full blown market design, we did recognize that there's
19 currently self-provision of the requirement from road-
20 serving entities.

21 Through the participation of those LSE's in their
22 regional reserve-sharing agreement, the sharing agreement
23 sets aside the transmission reserve margin, TRM, and also
24 establishes the requirements for how much reserve each party
25 is obliged to carry.

1 So at this stage even if initially the Midwest
2 ISO's market were to start on the first day of day 2 with a
3 contingency reserve market, absent some decision by the
4 market participants who are currently self-providing through
5 this grandfathered regional agreement, there would be no
6 clearing in that market because they are already meeting
7 that obligation.

8 I don't know if that addresses the issue of how
9 you identify scarcity of locational reserves. But I'm not
10 aware of a mechanism today whereby there's an explicit
11 process for establishing a requirement for locational
12 reserves in the MISO footprint.

13 MR. HELMAN: That was my point. I guess some of
14 the things we heard earlier were that New England, the
15 failure of the push mechanism, which was an attempt to
16 loosen the mitigation, the next steps in that would be to
17 have a locational capacity requirement or a locational
18 reserve requirement.

19 That was the direction the market design solution
20 is going on the East coast. That's not available in MISO.
21 So you're basically in a push-like situation.

22 MR. MCNAMERA: I think there is general
23 acceptance to a greater or lesser extent across stakeholders
24 -- certainly the MISO -- that we will move in that
25 direction. We don't think we need that in order to arrive

1 on December 1st.

2 MR. SINGH: You briefly mentioned that you were
3 going to rely on LSE contracts. The conventional wisdom is
4 that the prices in these contracts are a function of the
5 spot markets. With the mitigation there they are going to
6 have an impact on the compensating ability of any of these
7 contracts.

8 But I would think then that maybe that changes if
9 you mandate long-term contracts. I don't know if you think
10 that's important. Does it introduce a disconnect between
11 the spot market and spot markets and market power and some
12 of the long-term contracting?

13 MR. CASEY: I'm not entirely sure I understand
14 your question. You're saying if you mandate long-term
15 contracts for load-serving entities, would that create a
16 disconnect? And what those contracts would be valued at
17 relative to the spot market if you didn't mandate it?

18 MR. SINGH: Yes, because if I'm an LSE and I can
19 go between spot or forward, then, you know, if one is
20 mitigated, then I would go there -- if the center is
21 exercising market power in the long-term contract. But if
22 you as a regulator come to me and say you have to buy all of
23 your energy, 95 percent or some reserve margin long term,
24 then it's almost like it's a regulatory requirement. So
25 then you could have sellers charge prices that are not

1 necessarily a function of the mitigation of the spot market.

2 I was just wondering if that's correct.

3 MR. CASEY: I think it's important to keep in
4 mind that the contracting requirement doesn't necessarily
5 have to be for energy. It could be. Ideally you'd want the
6 flexibility to provide a mix of capacity contracts and long-
7 term energy contracts so you could make that trade-off.

8 I want to make sure I have sufficient capacity to
9 meet load three years from now, but it doesn't make sense
10 for me to buy 100 percent of my load requirement at that
11 point. So you could defer some of your price risk to the
12 spot market, but you'd have to procure all of your capacity
13 requirement.

14 If, by forcing a requirement on load-serving
15 entities, are you creating a market power problem? The
16 comments we offered -- because this issue did come up in the
17 PUC proceeding -- is that as long as you're looking out long
18 enough, several years or more, the load-serving entity has a
19 lot of options, because you're looking at building new
20 generation transmission so the market power issue then
21 becomes much less of an issue.

22 MR. BANDERA: Keith, can you explain what
23 capacity means in the context you just mentioned? You can
24 have a contract with capacity. I understand in the
25 Northeast ISO's, there's capacity that's subject to

1 mitigation and all that.

2 In the context that you're talking about with
3 these bilateral contracts between parties what does it mean
4 to procure capacity?

5 MR. CASEY: I think it would have the same
6 implications. If the load-serving entity had a capacity
7 contract with a supplier, the supplier would have to offer
8 that capacity into the day-ahead energy market and there was
9 a requirement that it be offered at a fixed price or perhaps
10 the contract said I'm not going to require a fixed price.
11 You are free to offer it at any price. I just want that
12 capacity to be there and bid into the market.

13 So I think it could work the same as it does in
14 the Eastern ISO's. It's just through a bilateral mechanism.

15 MR. BANDERA: It's not a bilateral mechanism just
16 where they're providing capacity to one LSE solely. So it
17 wouldn't be the generator is obligated to provide capacity
18 to the LSE and not to the market as a whole. Is there any
19 distinction?

20 MR. CASEY: That's certainly the way the ISO
21 views the capacity obligation should work. It should be
22 made available to the spot market because ultimately you
23 want to optimally dispatch that capacity.

24 I know in the context of the PCU proceeding that
25 was an issue of concern by a number of parties. If I

1 procure this capacity, I don't want it serving somebody
2 else's load.

3 So I think that's an issue that we'll have to
4 work through in some of the workshops that the PUC is
5 planning to hold on how you count capacity going forward.

6 MR. O'NEILL: Is the reason why they don't want
7 that capacity serving someone else's load is because the
8 spot market price is potentially too low?

9 MR. CASEY: I'm not prepared to speculate on the
10 rationale for that particular position.

11 MS. SHIPLEY: Can I just ask -- we heard earlier
12 from a load-serving representative from New York, who was
13 saying that New York City is a load pocket and they have
14 high prices. And that seemed appropriate to him.

15 MR. CASEY: I guess it again comes down to the
16 issue of what do you believe during down scarcity conditions
17 a competitive outcome would be.

18 I think the argument is the reason you're
19 mitigating in the first place is because you believe there's
20 a market power problem. So the way we approach it is, then
21 what should you try to accomplish by intervening in the
22 market mitigation?

23 Our view is to try to simulate as best you can,
24 albeit imperfectly, what a competitive outcome would yield.
25 And in our view that's the marginal cost of the highest cost

1 unit.

2 Now, the New York ISO has contract and impact
3 thresholds that essentially allow an acceptable level of bid
4 markup. But with all due respect, that's an acceptable
5 level of market power.

6 An argument is, well, those excesses can go to
7 fixed cost recovery and that's certainly true. But is that
8 a perfect instrument for providing fixed cost recovery?

9 And our argument is it's very imperfect. With
10 that type of mechanism there are going to be some resources
11 that are able to over-collect in terms recovering their
12 fixed costs. And there will be other resources where the
13 threshold is not high enough.

14 MR. O'NEILL: There's more than one explanation
15 for the flexibility that AMP allows. And one of them is
16 your inability to get marginal cost right exactly.

17 And I think, as Bob Ethier pointed out, in New
18 England the last couple of weeks, trying to get the spot
19 market price correct to put into your marginal price
20 calculation, you could have been off by a factor of two
21 without even working hard.

22 MR. CASEY: I certainly agree that trying to
23 estimate the marginal cost of unit is an imprecise science.
24 There's no question about that.

25 The reason we proposed the 10 percent bid adder

1 similar to PJM was to try to capture some of that. And I'm
2 sure some would argue that's not enough.

3 MR. BANDERA: Would market design rules be
4 different for generators that aren't in any long-term
5 bilateral contracts where the mitigation rules?

6 MR. CASEY: We're not proposing different rules
7 depending on supplier's contract positions.

8 MR. SINGH: I just want to ask one last question
9 on something Judi said. You said RMR contracts are causing
10 prices to be higher. Is that more a consequence of how they
11 are being used? Because if they were actually being used, I
12 would think the prices would be lower because of all of the
13 energy that would be in the market.

14 MS. MOSLEY: I think that's right. My comments
15 were directed primarily to the condition 2 contracts. Also
16 the fact that RMR is used more in northern California than
17 it is in southern California. In southern California they
18 found other tools to rely upon in order to mitigate,
19 including the must-offer requirement.

20 So my comments -- I'm not suggesting that RMR
21 contracts generally have no place at all. I think they are
22 still necessary, particularly for older, less efficient
23 units that would not be operating in the absence of a
24 contract. We'd have serious concerns with the condition 2
25 arrangements.

1 MR. O'NEILL: As I understand, the way you
2 describe the process, the RMR, costs get assigned directly
3 to PG&E. And the transmission upgrades get assigned to the
4 camp and the whole California foot-print. Why aren't you
5 building more transmission?

6 MS. MOSLEY: We're doing that too.

7 MR. MEYER: Could I just add a clarification? I
8 keep hearing or heard that RMR or fixed costs should not go
9 at all into the LLP. I'm not sure I really understand. It
10 seems to me like the best way to get the proper price
11 signals is to include some of the fixed costs in these areas
12 and to the LMP as opposed to giving RMR contracts.

13 I mean, we've already gone down the road,
14 particularly like in PJM, of the co-cost approach. Even
15 that oftentimes you could look at different units -- and
16 particularly the ones I'm worried about are the ones that
17 are small GT's, small load pockets.

18 I don't think capacity markets work with a load
19 pocket of one or 2 units. And if you locally run 2 or 3
20 percent of the time 200 hours a year, if you look at their
21 O&M cost, it's going to fall in a range between \$10 a kW to
22 \$20. That's going to work out from \$50 to \$100 a megawatt
23 hour spread out.

24 They are never in the market. You need it. How
25 in the world do you expect for them to recover any money and

1 stay there if you don't know why they put that fixed cost in
2 the LMP?

3 MR. O'NEILL: As Mike Schnitzer testified, there
4 are four or five cases where you do different things because
5 of the situation.

6 My own personal feeling is that as soon as we
7 start getting involved in making fixed cost calculations,
8 sunk cost calculations -- and I realize that your O&M is
9 really a variable cost going forward, so that's a different
10 story.

11 But as we start getting into fixed cost
12 calculations, we're on that slippery slope that people
13 talked about this morning. The cost of service regulation
14 is the whole issue -- that we let you recover your fixed
15 cost in the market and not here at FERC.

16 MR. MEYER: That's why we proposed other ways to
17 do it. The point is you have to allow enough offer cap. If
18 you're going to mitigate in a load pocket, you have to allow
19 enough offer cap for most units in there or all units to
20 recover their basic fixed costs. If you don't, they'll
21 retire.

22 MR. O'NEILL: We're not going to let you retire.
23 We need the minimum to let you recover your going forward
24 costs.

25 MR. GRAMLICH: You've given a good advertisement

1 for tomorrow's conference, looking down David Patton's list
2 of priorities. But an alternative source of economic
3 signals. He said the location specific operating markets
4 would work in that case. Locational capacity markets
5 wouldn't work in that case.

6 It sounds like you would put number four ahead of
7 number three. Your design next best option would be a
8 relatively loose market power mitigation measure.

9 MR. MEYER: Determine when you need it. For
10 instance, we move from 10 percent on a lot of those units to
11 a to-go cost -- I think of \$40. Ten percent was probably \$8
12 or \$9 or \$10 versus \$40.

13 The use of those units went down appreciably,
14 which to me indicated the LMP selection, that they really
15 didn't have local market power all the time anyway. So we
16 were mitigating time lines.

17 And I don't know how to make that clear
18 distinction. I laid out some principles. I don't have
19 perfect solutions to it. But somehow we got to make those
20 work.

21 MR. GRAMLICH: The other option on here is an RTO
22 option. That's the proposal on the table for tomorrow.

23 CHAIRMAN WOOD: Let me ask you a question,
24 Danielle and John. You ran out of time to say what the
25 solution is. I was involved in setting up the old solution,

1 so I'm kind of hanging with dated breath to know what the
2 new solution is.

3 MS. JAUSSAUD: The new solution now under
4 consideration -- it hasn't been adopted that this is what we
5 have on the table in terms of compensation for delivery out
6 of merit when there's not a market solution.

7 The market participants have discussed
8 compensating at generic costs. But there are various
9 different kinds of generic costs. One proposal was to
10 compensate. And that goes back to what Keith was saying --
11 compensate all generators, regardless of their resource, at
12 the level of the most inefficient unit in the local market.

13 We have set approximately a heat rate of 18,000
14 Btu's. Most of these are gas units. So this would have
15 compensated a new, efficient unit a lot more than an old,
16 inefficient unit. And the idea was that this would attract
17 investments of new, efficient plants.

18 But this proposal was rejected by the
19 stakeholders because -- number 6 on my list of issues
20 was the price impact was going to be too high for those
21 stakeholders, who were participating in the discussion.

22 Those who were in favor of that solution were the
23 new entrants through the combined cycles and the RPPS.**

24 The market participants were looking for a
25 solution that was similar to that but not quite as expensive

1 to the market. And again it comes back to the idea of not
2 compensating the inefficient unit more than the efficient.

3 They brought a lead to the generic costs of this
4 category, a percentage. One of the ideas was to have a
5 different percentage, a higher percentage, for the
6 inefficient unit and a lower percentage -- I'm sorry, the
7 opposite -- a higher percentage for the efficient unit, a
8 lower percentage for the inefficient unit.

9 This way the net revenue, which is the total
10 revenue line -- net revenue would be equalized across the
11 board. That was also rejected. I think it was because the
12 formula used was a little too complicated. What is being
13 envisioned now is to have a heat rate adder. If the heat
14 rate is seven, for example, then your compensation will --
15 your generic costs will be calculated on the basis of a heat
16 rate of eight, let's say.

17 And that also is considered a formula that would
18 allow an equalization of the compensation and would not
19 favor the deployment of inefficient units.

20 CHAIRMAN WOOD: How much of the market does this
21 get triggered by? How much of the time does this get
22 triggered in the market? Is it localized to the DFW region
23 or what?

24 MS. JAUSSAUD: A lot of it is in the DFW region.
25 This is where the most important load pocket in ERCOT is.

1 The generation that is all around the DFW area is trying to
2 export into the DFW area but can't because of the
3 transmission constraints.

4 In the example that I cited the new generator was
5 built once again outside of the DFW area in an area where
6 there is generation that would be needed in the DFW area but
7 just can't flow through. That is the problem that's being
8 addressed.

9 MR. MEYER: I think Danielle's addressing the
10 current solutions as opposed to we're going to an LMP with
11 probably a different approach. We're still probably
12 wrangling over what's the right competitive test to make.

13 The DFW will almost always be an issue. It's
14 going to be in New York City. In fact it has probably more
15 load, I would say, than New York City. I'm not sure how big
16 New York City is. But I would assume DFW is about 20,000
17 megawatts. I think that's quite a bit larger than New York
18 City in megawatts.

19 So it's a big area. As you know, it's totally
20 constrained by regulation. New entry is almost impossible
21 within certain bounds. And transmission.

22 So there will be some mitigation in there. And I
23 think what's being proposed is more or less a bid cap in the
24 local market pocket. And we haven't set one yet.

25 So I'm going to talk -- some have talked of a

1 fixed heat approach. Some have talked. We've offered the
2 survey unit approach -- I should say, not widely accepted
3 there.

4 But given the load there, I can't quite
5 understand it. But anyway, there's got to be some way to
6 handle that. And I don't know.

7 The proxies I thought Danielle was talking about
8 is more when they do an out of market call. It's a command
9 and control. It's not using any sort of LMP calculation.
10 Of course, I guess we have to roll it into it if we're
11 really going to get LMP.

12 MS. JAUSSAUD: We probably would not implement
13 LMP until 2007. So we do have to find a solution in the
14 meantime.

15 MR. MEYER: But we have the same issues everyone
16 else has. And that big a load pocket -- it's quite
17 dramatic.

18 MR. COLEMAN: I'd like to thank the panelists for
19 spending their time with us giving us their comments. With
20 that, we'll conclude our conference for today. Thanks.

21 (Whereupon, at 4:50 p.m., the conference was
22 recessed until 9:00 the next day.)
